RP342

INDEX

- ABABEL, L. et al.** : Enzyme Regulatory Mechanisms at the Level of Lactate-oxidoreductase in Erythrocytes and Ascites Tumour Cells, 185
- Abbot, A., and Mitchell, J.** : Ultrastructure of the Antigen-retaining Reticulum of Lymph Node Follicles as shown by High-resolution Autoradiography, 500
- Abbott, Dr. D. C., Harrison, R. B., Tatton, J. O'G., and Thomson, Dr. J.** : Organochlorine Pesticides in the Atmospheric Environment, 1317
- Abe, M., Monig, H., and Koch, R.** : Influence of Oxygen and Cysteine on the Radical State of X-irradiated Lyophilized Liver, 499
- Abelson, Dr. D. M.** : Ultra-violet Spectroscopy in the Analysis of Chromatograms, 784
- Aberdeen, University of, Appointments, 436**
Chair of Genetics, 436, 833
Professor of Inorganic Chemistry, 20
- Aberdeenshire** : Corona Structures in the Basic Igneous Masses of East (Dr. D. S. Weedon), 885
- Abnormal Fibrinogen (Fibrinogen Baltimore)** : New Inherited Coagulation Disorder caused by an (Dr. E. A. Beck et al.), 143
- Aborigines** : Haptoglobin Johnson in Australian (D. W. Cooper et al.), 694
- Hereditary Ovalocytosis and Haemoglobin E-Ovalocytosis in Malayan (Dr. Lie-Injo Luan Eng), 1329**
- Portraits of Tasmanian, 230**
- Abraham, Prof. E. P.** : Antimicrobial Agents and Chemotherapy—1964, review, 980
- Absence of Diffusion Control of Reaction Rate in the Thermal Decomposition of Amorphous Polymers (D. A. Smith), 1200**
- Absolute Determination of the Acceleration due to Gravity at the National Physical Laboratory** : New (Dr. A. H. Cook), 279
- Absorption and Emission** : Anomalous Intensity Ratios of the Interstellar Lines of OH in (R. X. McGee et al.), 1193
- Absorption by the Perfused Small Intestine of Amphibia** : Hydrolysis of Disaccharides during (Dr. D. S. Parsons and J. S. Prichard), 1097
- Absorption of Carbon Dioxide by Plants** : Influence of Hexadecane on (Prof. J. M. Riedhart), 300
- Absorption of Fat** : Use of Polyethylene Glycol in Investigations of (Dr. H. Vavřínková and Dr. A. Kroudl), 293
- Absorption Spectra of Aromatic Nitrenes and Dinitrenes** : Ultra-violet (A. Reiser and V. Frazer), 682
- Absorption Spectrum of the CH₃O-radical** : Electronic (J. F. Ogilvie), 1315
- Absorption** : Transport of Methionine and Sodium Butyrate by Intracellular Plasma Mechanism of Intestinal (S. L. Hart and Dr. J. A. Nissim), 145
- (Acanthocytosis)** : Precipitin Activity in the Sera of Patients with Deficiency of β -Lipoproteins (Dr. R. F. Murray, jun., and Prof. B. S. Blumberg), 357
- Acceleration due to Gravity at the National Physical Laboratory** : New Absolute Determination of the (Dr. A. H. Cook), 279
- Accidents** : Cerebrovascular, 734
- Accretion in the Solar Nebula** : Enrichment of Iron during (Prof. S. R. Taylor), 886
- Accumulation and Incorporation of Amino-acid in Rat Intestine in vitro (Dr. J. R. Bronk and Dr. D. S. Parsons), 785**
- Accumulation of Keto-acids in Tissues during Diphtheria Intoxication (Dr. S. C. Agarwal), 914**
- Acetohydroxamate** : Bacterial Urease Inhibitor with Therapeutic Potential in Hyperammonaemic States (Dr. W. N. Fishbein and P. P. Carbone), and (H. D. Hochstein), 46
- N-Acetyl Neuraminic Acid Terminating Receptors for Myxovirus Attachment** : Nuclear Surface (Prof. P. I. Marcus et al.), 1122
- Acetylcholine on the Heart of the Mollusc *Tapes turrida*** : Biphasic Dose-response Relationship with (P. R. Carroll and G. B. Chesher), 1220
- Achondrites** : Abundances of Rare Earth Elements in Eclogitic Rocks and Basaltic (J. W. Morgan and Dr. J. F. Lovering), 1311
- Acid Mucopolysaccharide and Hexosamine Metabolism in Dermal Connective Tissue of Adrenalectomized Rats (Prof. J. Fabianek, Dr. A. Herp and Dr. L. Martinez), 1212**
- Acid Mucopolysaccharides** : Chemical Physiology of the (J. E. Scott), 1270
- Acid Phosphatases (Dr. C. A. Vernon, J. Gaudie, J. M. Hanson, J. M. Humphreys, P. E. Smith, A. J. Lawrence and Dr. B. E. C. Banks), 382**
- Acid Soils** : Measurement of Exchangeable Aluminium in (J. B. Skeen and Dr. M. E. Sumner), 712
- Ackman, Dr. R. G.** : Occurrence of Odd-numbered Fatty Acids in the Mullet *Mugil cephalus*, 1213
- Acoustic Velocity Dispersion in some Non-associated Organic Liquids (Dr. S. E. A. Hakim and W. J. Comley), 1082**
- Acridine Orange by Polyribonucleotides** : Heterogeneous (Prof. R. F. Beers, jun., and G. Armile), 466
- Acrylamide-gel Electrophoresis of β -Lactoglobulins stored in Solutions at pH 8.7 (Dr. P. Akroyd), 488**
- Acrylamide-gel Electrophoresis** : Quantitative Determination of Haemoglobin A₂ by (Lieut.-Commander T. G. Ferris et al.), 1103
- Acrylamide Gels** : Taxonomic Investigation of Several Brassica Species using Serology and the Separation of Proteins by Electrophoresis on (Dr. J. G. Vaughan et al.), 704
- Actinomycin D** : An *in vitro* Action of Human Growth Hormone in the Presence of (T. E. Martin and Prof. F. G. Young), 684
- Rapidly Labelled Synthesis of Ribonucleic Acid in Ehrlich Ascites C-2 Tumour Cells treated with (D. A. Popović), 49**
- Stimulation of Sendai Virus Multiplication by Puromycin and (Dr. D. O. White and I. M. Cheyne), 813**
- Activation of Muscle Differentiation** : Replication and the (Dr. P. Pietsch and S. B. McCollister), 1170
- Activation of Spores of *Penicillium roqueforti* (R. C. Lawrence), 801**
- Acute Radio-sensitivity as a Function of Age in Mice (Dr. J. F. Spalding, O. S. Johnson and R. F. Archuleta), 905**
- Acylating Agent** : Thalidomide as a Possible Biological (S. Fabro et al.), 1208
- Adams, Dr. D. M., and Morris, D. M.** : Far-infra-red Spectra of some Square-planar Ions, 283
- Adams, Roy M. (edited by)** : Boron, Metallo-Boron Compounds and Boranes, review by Dr. L. H. Long, 968
- Adaptive Growth (Prof. R. J. Goss), review by Dr. R. A. Weiss, 107**
- Aden Protectorate** : Stratigraphy and Structure of the Eastern (Dr. Z. R. Beydoun), review by E. E. Wellings, 615
- Adenine-specific Antibodies with Denatured Deoxyribonucleic Acid** : Reaction of (Dr. S. Estrada-Parra et al.), 1010
- Adenosine Di- and Tri-phosphates in the Presence of Calcium Phosphate Precipitates** : Transphosphorylation of (Dr. R. W. Burley), 683
- Adenosine Diphosphate-induced Aggregation of Human Platelets** : Plasma Co-factors in (Dr. D. Deykun et al.), 296
- Adenosine Monophosphate and Melanocyte-stimulating Hormone on Frog Skin in vitro** : Effects of Cylic (Dr. M. W. Bitensky and S. R. Burstein), 1282
- Adenosine Triphosphatase Systems of Rat Liver Mitochondria** : Stoichiometry of Proton Translocation through the Respiratory Chain and (Dr. P. Mitchell and Dr. J. Moyle), 147
- Adenosine Triphosphate-Metal-Norapinephrine Ternary Complexes and Catecholamine Binding (Dr. R. W. Colburn and Dr. J. W. Maas), 37**
- Adenovirus** : Association of, with Bovine Respiratory Disease (Dr. J. H. Darbyshire et al.), 307
- Adenovirus 7 and SV 40** : Mixed Infection of African Green Monkey Cells by (Dr. R. K. Wertz et al.), 1350
- Adgie, R. L., Gent, H., Slee, O. B., Frost, Prof. A. D., Palmer, Dr. H. P., and Rowson, Dr. B.** : New Limits to the Angular Sizes of Some Quasars, 275
- Adrenal Cortex in the Appearance of Rat Slow Alpha-Globulin** : Involvement of the (Prof. W. G. Ham and S. R. Ellenson), 1330
- Adrenal Medulla by Muscarinic and Pilocarpine** : Preferential Release of Adrenaline from the (Prof. W. W. Douglas and Dr. A. M. Poisner), 1102
- Adrenalectomized Rats** : Acid Mucopolysaccharide and Hexosamine Metabolism in Dermal Connective Tissue of (Prof. J. Fabianek et al.), 1212
- Adrenaline from the Adrenal Medulla by Muscarinic and Pilocarpine** : Preferential Release of (Prof. W. W. Douglas and Dr. A. M. Poisner), 1102
- Adrenals** : Aldosterone Secretion : Differences in Direct Effects of Rubidium and Potassium Perfusion into Dog (Prof. J. G. Hilton et al.), 1099
- Adrenergic Vasodilation** : Pronethalol-induced Reversal of (Dr. M. G. Moreira and Dr. W. Osswald), 1006
- Adrian, The Lord** : A History of the Rockefeller Institute 1901-1953, review, 1244
- Adsorption and the Differential Capacitance of the Electrical Double-layer at Platinum/Halide Metal Interfaces (A. D. Graves and Dr. D. Inman), 481**
- Adult Behaviour in Rats** : Effect of Foster-mothers' Strain and Pre-natal Experience on (Dr. J. M. Joffe), E15
- Adults and pre-School Children's Scribbles** : Form-similarity between Phenomena of (R. Kellogg et al.), 1129
- Advances in Enzyme Regulation, Vol. 2, (edited by G. Weber), review by C. J. R. Thorne, 319**
- Aeronomy and Ice Sheets** : Antarctic (Dr. G. de Q. Robin), 439
- 'Aerosil'** : Infra-red Spectra of Quaternary Ammonium Compounds adsorbed on Silica-gel (Dr. L. C. F. Blackman and R. Harrop), 777
- Aerosol Particles** : Ultra-purification by Separation of (Dr. S. Behrendt), 581
- Aetiology for Down's Syndrome (Mongolism)** : Virus (A. Stoller and R. D. Collmann), 903
- Aflatoxin** : Effect on Cultured Heteroploid Human Embryonic Lung Cells (Dr. M. S. Legator, S. M. Zuffante and A. R. Harp), 345
- Africa** : Introduction to the Flowering Plants of West (Mrs. M. Steentoft Nielsen), review by F. N. Hepper, 976
- Malaria and the Opening-up of Central (R. Weatherall), 1267**
- Meat from Wild Animals in, 122**
- 'Africa'** : "There is all (Dr. A. S. Thomas), 16
- African Green Monkey Kidney Cells by Adenovirus 7 and SV 40** : Mixed Infection of (Dr. R. K. Wertz et al.), 1350
- African Mammals, 1046**
- African (South) Prehistory, 22**
- African Students in Britain, review by Lord Twining, 957**
- African Wildlife** : Research and Management in East (Dr. J. Morton Boyd), 828
- Agar-Agar Diffusion Procedure to Pesticide Residue Analysis and to the Cholinesterase Screening of Candidate Pesticides** : Application of an (Dr. K. I. Beynon and G. Stoydn), 748
- Agar-gel Electrophoresis of Soluble Lens Proteins in Galactose-fed Rats (E. Wittgenstein and Dr. K. W. Rowe, jun.), 386**
- Agarwal, Dr. S. C.** : Accumulation of Keto-acids in Tissues during Diphtheria Intoxication, 914
- Age** : Altered Electrophoretic Mobilities of some Erythrocytic Enzymes as a Function of their (Dr. H. Walter et al.), 76
- Age** : Memory Changes with (Prof. D. Schonfield), 918
- Age and of Hypoxia** : Life-shortening in Mice exposed to Radiation Effects of (Dr. P. J. Lindop and Prof. J. Rotblat), 1070
- Age Determinations of North American Rocks, 435**
- Age in Mice** : Acute Radio-sensitivity as a Function of (Dr. J. F. Spalding et al.), 905
- Age of the Weardale Granite (F. J. Fitch and Dr. J. A. Miller), 743**
- Aged Mice** : Multiple Thyroid Grafts in (Dr. D. Metcalf), 87
- Ageing and in Prolapse** : In efferential Matrix of the Intervertebral Disk in (Dr. T. K. F. Taylor and Dr. K. Little), 384
- Ageing in Eastern Europe** : International Conference on Gerontology, review by Dr. David A. Hall, 981
- Ageing** : Transplantation Experiments on Placental (R. L. Simmons and J. Weintraub), 82
- Ages and Andean Uplift** : Isotopic (Dr. R. W. R. Rutland et al.), 677
- Ages** : Wilson's Theory of (J. T. Hollin), 12

- Agfa-Gevaert AG Leverkusen-München : Mitteilungen aus den Forschungslaboratorien der, Band IV, (edited by Prof. E. Klein and R. Matejec), review by K. O. Ganguin, 720
- Agglutination : Mathematical Model for the Process of Aggregation in Immune (T. K. Ming *et al.*), 84
- Agglutinin in the Snail *Helix (Helix) lactea* : A Specific (Prof. W. C. Boyd and R. Brown), 593
- Aggregates as a Cause of Failure in Concrete : Shrinking, 1261
- Aggregating and Take-off in Anthophorid Bees, *Anthophora acraensis* Fab. : Periodic (Prof. L. K. H. Goma), 807
- Aggregation and Electric Shock in Mice treated with Cocaine : Lethal Effects of (H. Lal and Dr. R. D. Chessick), 295
- Aggregation in Immune Agglutination : Mathematical Model for the Process of (T. K. Ming *et al.*), 84
- Aggregation of Human Platelets : Plasma 60-factors in Adenosine Diphosphate-induced (Dr. D. Deykin *et al.*), 296
- Aggressive Behaviour, Mental Subnormality and the XYY Male (P. A. Jacobs, M. Bruntom, M. M. Melville, Dr. R. P. Brittain and Dr. W. F. McClelland), 1351
- Agricultural Engineering : Component Failure Investigation : National Institute of, 1262
- Agricultural History, 1939-64 : Dutch Study Circle for, review by G. E. Fussell, 1138
- Agricultural Problems in Co. Limerick, Eire : Regional Geochemical Reconnaissance applied to some (Prof. J. S. Webb and W. J. Atkinson), 1056
- Agriculture, Shambat : University of Khartoum, Sudan : Silver Jubilee of the Faculty of (Prof. M. A. Nour), 620
- Aid Overseas : British Government, 1153
- Aid to Developing Countries : British, 128
- Aid to Education Overseas, 120
- (*Alurupoda melanoleuca*) : Bursa Pharyngea in the Giant Panda (Prof. A. J. E. Cave), 865
- Air Ion Effects on the Oxygen Consumption of Barley Seedlings (S. Kotaka, Prof. A. P. Krueger, P. C. Andriese, K. Nishizawa, T. Ohuchi, M. Takenobu and Y. Kozure), 1112
- Air : Towards a University of the, 715
- Aircraft : Anglo-French Military, Project Director for *Jaguar* Strike/Trainer, 527
- Aitken, Prof. A. C. : Retirement from Chair of Mathematics in the University of Edinburgh, 832
- Aiya, Prof. S. V. C. : Some Characteristics of Tropical Thunderstorms, 641
- Akroyd, Dr. P. : Acrylamide-gel Electrophoresis of β -Lactoglobulins stored in Solutions at pH 8.7, 488
- Alais and Orgueil Carbonaceous Meteorites : Evidence for Microfossils in the (S. L. Van Landingham), 947
- (α 5 Alanine \rightarrow Aspartic Acid) : A New Haemoglobin, J Toronto (Dr. J. H. Crookston *et al.*), 1059
- Alaskan Mammals, 936
- Albert Lasker Medical Research Awards, 1263
- Albumin Antibody : Rapid Detection and Titration of Antihuman Serum (Dr. M. S. Tobin), 1338
- Alcohol and Evoked Potentials in the Cat (A. K. Schweigert, Dr. A. R. David, A. H. Stewart and Dr. H. E. Himwich), 688
- Alderson, Dr. T., and Khan, A. H. : Mutagenic Effect of Irradiated and Unirradiated DNA in *Drosophila*, 700
- Aldosterone in Myocardial Infarction, 836
- Aldosterone Secretion : Differences in Direct Effects of Rubidium and Potassium Perfusion into Dog Adrenals (Prof. J. G. Hilton, Dr. S. Alter and Dr. P. Cushman), 1099
- Aldrin or Dieldrin : Metabolites in Urine of Rats on Diets containing (P. R. Datta *et al.*), 289
- Alexander, W. M., *et al.* : Measured Velocities of Interplanetary Dust Particles, 673
- Alfred, Lawrence J. : Differential Inhibition of Deoxyribonucleic Acid and Ribonucleic Acid Synthesis induced in Cultured Mammalian Cells by 7-12-Dimethylbenzanthracene, 1339
- Algae : Biology of the (Dr. F. E. Round), review by Dr. M. Parke and G. T. Boalch, 824
- Algard, Prof. F. T., Dodge, A. H., and Kirkman, Prof. H. : Androgen-Gestrogen-induced Tumours : Lactic Dehydrogenase Relative to Chaeptithelioma Induction in the Syrian Hamster, 567
- ALGOL 60 Implementation (B. Randall and L. J. Russell), review by I. M. Khabaza, 217
- Alkali, etc. Works : Inspection of, One Hundred and First Annual Report on, 1964, 234
- Alkaline Earth Metals, Handbuch der Experimentellen Pharmakologie. Band 17. Two Volumes in French (Zénon-Marcel Bacq, sub-editor), review by Prof. E. Zaimis, 720
- Alkaline Hydrolysis of Glycine Ethyl Ester : Protonation Equilibria and (Dr. M. Robson), 265
- n-Alkan-1-ols in Butter after Oxidative Deterioration (W. Stark and D. A. Forss), 190
- Allan, Dr. D. : Manual for the Identification of Medical Bacteria, review, 213
- Theory and Practice in Experimental Bacteria, review, 213
- Allan, Dr. N., Beale, D., Irvine, D., and Lehmann, Dr. H. : Three Haemoglobins K : Woolwich, an Abnormal, Cameron and Ibadan, Two Unusual Variants of Human Haemoglobin A, 658
- Allatectomized Males and Females on the Sexual Maturation of Young Male Adults of *Schistocerca gregaria* (Forsk.) (Orthoptera : Acrididae) : an Inhibitory Effect of (M. J. Norris and M. P. Pender), 1122
- Alleles in Different Botanical Varieties of *Brassica oleracea* : Identical S (K. F. Thompson and J. P. Taylor), 306
- Allen, Dr. Gordon : A Search for Mutation in Chemical Systems at Steady State, 258
- Allen, H. W., and Jolley, Dr. W. B. : Formation of Complexes between Basic Proteins of Leucocytes and Plasma Globulins, 390
- Allen, Dr. John : Laminar and Turbulent Flow in Open Channels, 1196
- Allen, J. R. L. : Atlas and Glossary of Primary Sedimentary Structures, review, 315
- Allen, Prof. P., and Keith, Prof. M. L. : Carbon Isotope Ratios and Palaeosalinities of Purbeck-Walden Carbonates, 1278
- Allergy : Direct Reaction of Penicillin with ϵ -Amino-groups : New Chemical Aspect of Penicillin (Dr. C. H. Schneider and Dr. A. L. de Weck), 57
- Allergy : Fresh Approach to the Problem of, 530
- Allogenic Inhibition of Tumour Cells by *in vitro* Contact with Cells containing Foreign H-2 Antigens (K. E. Hellstrom, I. Hellstrom and C. Bergheden), 458
- Allografts in Thymectomized X-irradiated Dogs : Bone Marrow (I. L. Chertkov *et al.*), 399
- Alloys : Dispersion-softened Zinc (W. H. McCarthy *et al.*), 579
- Allsopp, Dr. A. : Strasburger's Textbook of Botany, New English Edition, review, 618
- Alpha Activity of Drinking Water using a Nuclear Emulsion : Determination of the Total (M. W. Tyrrell *et al.*), 1074
- Alps : Oil Pipeline over the, 435
- Alter, Dr. S., *et al.* : Aldosterone Secretion : Differences in Direct Effects of Rubidium and Potassium Perfusion into Dog Adrenals, 1099
- Alteration of Hamster Cells by Nucleic Acid *in vitro* (K. Shepley, Dr. E. J. Ambrose and Dr. K. S. Kirby), 1072
- Altered Electrophoretic Mobilities of Some Erythrocytic Enzymes as a Function of their Age (Dr. H. Walter, F. W. Selby and J. R. Francisco), 76
- Altered Perfusion Rates : Effect of, on the Retention of Noradrenaline by the Spleen (Dr. D. M. Paton and Prof. C. N. Gillis), 391
- A.C. Resistivity of Anodic Oxide Films on Valve Metals (Dr. G. C. Wood and C. Pearson), 547
- Alternating Current Stimulation : Squid Giant Axon : Repetitive Responses to (Prof. H. R. Hirsch), 1218
- Aluminium, Germanium and Silicon to 60 kilobars : Fusion Curves of Zinc, (J. Lees and B. H. J. Williamson), 278
- Aluminium in Acid Soils : Measurement of Exchangeable (J. B. Skeen and Dr. M. E. Sumner), 712
- Aluminium-Silicon Eutectic : Interconnexion of Silicon in Modified (J. A. E. Bell and Prof. W. C. Winegar), 177
- Amazon : A Visit to the Lower (I. R. Bishop and Prof. G. E. H. Foxon), 114
- Ambrose, Dr. E. J., *et al.* : Alteration of Hamster Cells by Nucleic Acid *in vitro*, 1072
- American Forms : Marsupial Spermatozoa Pairing in the Epididymis of (Dr. J. D. Biggers and Dr. E. D. DeLamater), 402
- American Geographical Society : Awards, 1047
- America (North) : Bark Canoes and Skin Boats of, 22
- American (North) Rocks : Age Determinations of, 435
- American Society of Plant Physiologists : Awards, 231
- Officers, 231
- Amides : Slow Inversion at the Nitrogen Atom in Certain (Dr. T. H. Siddall and Dr. C. A. Prohaska), 582
- Amines in the Gastric Mucosa of the Rat : Formation of (R. Håkanson), 793
- Amino-acid in Rat Intestine *in vitro* : Accumulation and Incorporation of (Dr. J. R. Bronk and Dr. D. S. Parsons), 785
- Amino-acid Sequence of β -LPH from Sheep Pituitary Glands : Isolation and (Prof. Choh Hao Li *et al.*), 1093
- Amino-acids as Trimethylsilyl Derivatives : Quantitative Gas Chromatography of (Prof. E. D. Smith and H. Sheppard, jun.), 878
- Amino-acids from Proteins : Freeing of (Dr. L. J. Hastewell and R. N. Priestland), 387
- Amino-acids from the Resting Human Forearm : Evidence for the Release of Individual (Dr. D. R. London and Dr. T. H. Foley), and (C. G. Webb), 588
- Amino acids : Polyamide Layer Chromatography of DNP (Prof. Kung-Tsung Wang and J. Mei-Kuo Huang), 281
- ϵ -Amino Group of Collagen : Reactivity of the (J. H. Bowes *et al.*), 1094
- ϵ -Amino-groups : New Chemical Aspect of Penicillin Allergy : Direct Reaction of Penicillin with (Dr. C. H. Schneider and Dr. A. L. de Weck), 57
- Aminoacyl Naphthylamidase in the Rat : Source of Blood (Dr. B. Monis), 587
- 2-Aminoethanephosphonic Acid : a Phosphoramidic Acid Rearrangement : Biosynthesis of (Dr. W. Segal), 1284
- 2-Aminoethyl-guanidine and of a Eugenol as Virus Inhibitors : Derivatives of (S. Pácsa *et al.*), 409
- Amino-nitrogen Content of Solutions of γ -Keratoase from Wool Keratin : Changes in (Dr. R. S. Asquith and P. A. Watson), 786
- (Aminopeptidase) Isozymes of Arylamidase (Dr. B. Monis), 587
- Ammonium Compounds adsorbed on Silica-gel 'Aerosil' : Infra-red Spectra of Quaternary (Dr. L. C. F. Blackman and R. Harrop), 777
- Amodio, Dr. A., *et al.* : Distribution of the Intestinal Factor in Normal Mice which inactivates Murine Virus Hepatitis, 1009
- Amorphous Polymers : Absence of Diffusion Control of Reaction Rate in the Thermal Decomposition of (D. A. Smith), 1200
- Amos, T. G. : Kinesis, 908
- Amount and Composition of the Serum Seromucoid Fraction : Factors affecting the (Dr. A. J. Anderson), 491
- Amphibia : Hydrolysis of Disaccharides during Absorption by the Perfused Small Intestine of (Dr. D. S. Parsons and J. S. Prichard), 1097
- Amphibians : Enzymatic Synthesis of the Skin-lightening Agent, Melatonin, in (Dr. J. Axelrod *et al.*), 386
- Ampicillin : Crystalline Modifications of (K. W. B. Austin *et al.*), 999
- Amylase-levels in the Human Male and Female : Comparison of Salivary (Prof. R. L. McGeachin *et al.*), 1211
- Anaemia? : A Sex-dependent Factor in Aplastic (Dr. D. E. Pegg and J. E. Burns), 1187
- Analogy : Biological and Mental Evolution : an Exercise in (Arthur Koestler), 1033
- Analysis : Concentration Effects in Chromatographic (Prof. I. D. Rattee *et al.*), 269
- Counterexamples in (Prof. B. R. Gelbaum and Prof. J. M. H. Olmsted), review by Prof. T. A. Broadbent, 218
- Analysis in the Sub-sieve Range by Electronic Counter : Size (Prof. C. C. Harris and Dr. A. Jowett), 175
- Analysis of Chromatograms : Ultra-violet Spectroscopy in the (Dr. D. M. Abelson), 784
- Analysis of Organic Acids by Tritiating Methylation : Quantitative Chromatographic (G. K. Koch and [the late] G. Jurriens), 1312
- Analysis of Surface-active Agents by Infrared and Chemical Methods : Identification and (Prof. D. Hummel), Two Volumes, review by Dr. P. Robson, 617
- Analysis of Vibration : Matrix (Prof. R. E. D. Bishop *et al.*), review by Prof. W. A. Tuplin, 616
- Analysis : Structure, Behavior and Application to Inorganic, Organic Complexing Reagents (D. D. Perrin), review by Dr. T. S. West, 3
- Analytical Chemistry : Organic Complexing Reagents (D. D. Perrin), review by Dr. T. S. West, 3
- Anaphylactic Release of Vascular Permeability Factor or Histamine by Specific Protease Inhibitor in Tissue Culture : Inhibition of (Prof. H. Hayashi *et al.*), 1007
- Anatomical Changes associated with Juvenile-to-Mature Growth Phase Transition in *Hedera* (J. R. Goodin), 504
- Anatomie des Menschen : Histologie und Mikroskopische (Dr. W. Bargmann), 5th German Edition, review by Dr. G. Sander, 109
- Ancestry of Sea-stars (Dr. G. M. Philip) : (Prof. H. B. Fell), 766
- Andean Uplift : Isotopic Ages and (Dr. R. W. R. Rutland *et al.*), 677
- Andersen, A. J. : Uptake by Plants of Radiotracer from Contaminated Soils, 195
- Anderson, Dr. E. S. : A Rapid Screening Test for Transfer Factors in Drug-sensitive Enterobacteriaceae, 1016
- Anderson, Dr. E. S., and Lewis, Dr. M. J. : Characterization of a Transfer Factor associated with Drug Resistance in *Salmonella typhimurium*, 843
- Anderson, Dr. A. J. : Factors affecting the Amount and Composition of the Serum Seromucoid Fraction, 491
- Anderson-Berry Prize, 1966 : David, 530

INDEX

 Pituitary Glands : Isolation and Amino-acid Sequence of β -LPH from Sheep (Prof. Choh Hao Li *et al.*), 1093
 Pituitary *in vitro* : Direct Action of Thyroxine on the Trout (Dr. B. I. Baker), 1234
 Pituitary of the Eel : A Dual Neurosecretory Innervation of the Pars Distalis of the (Sir Francis Knowles and L. Vollrath), 1343
 Pituitary Transplants in the Teleost, 123
 Placental Ageing : Transplantation Experiments on (R. L. Simmons and J. Weintraub), 82
 Placental Protein with Immunological Similarity to Human Growth Hormone : Further Purification and Characterization of a (Dr. H. Friesen), 1214
 Planarian : its Significance in Biochemical Evolution : Arginine and Urea Biosynthesis in the Lard (Prof. J. W. Campbell), 1299
 Planet called Earth (Prof. George Gamow), review by Patrick Moore, 961
 Planet Mercury : Rotational Period of the (W. E. McGovern *et al.*), 375
 Planet Mercury : Rotational Period of the (Dr. G. Colombo), 575
 Planetary Surface Conditions : Lunar and (Dr. N. A. Weil), review by Dr. G. Fielder, 961
 Planets and Satellites : Tidal De-spin of (Dr. P. Goldreich), 375
 Planktonic Foraminiferal Biostratigraphy of the Neogene : Progress in the (Dr. F. T. Banner and Dr. W. H. Blow), 1164
 Planning a New Medical School, 634
 Planning : Political and Economic (P.E.P.), Annual Report, 229
 Plant Breeding : Genetic Principles and (Prof. W. Williams), review by Dr. K. Jones, 7
 Plant Breeding Station : Scottish, Director, 228
 Plant Cells : Pectic Polysaccharides in the Growth of (S. E. B. Gould *et al.*), 876
 Plant Cells : their Relation to Growth and Growth Induction : Direct and Indirect Effects of Radiation on (Dr. R. D. Holsten *et al.*), 850
 Plant-growth Regulators : Morphactins, a Novel Group of (G. Schneider *et al.*), 1013
 Plant Growth Substances in Earthworms demonstrated by Paper Chromatography and the Went Pea Test : Presence of (R. L. Nielson), 1113
 Plant Material : Rapid Method for Selenium Assay of (R. Duff and Prof. M. Chessin), 1001
 Plant Physiologists : American Society of, Awards and Officers, 231
 Plant Physiology : Encyclopedia of (edited by W. Ruhland), Vol. 15, Two Parts, review by Dr. C. R. Metcalfe, 619
 Plant Physiology in Canada (Prof. J. A. Webb), 27
 Plant Pigments : Chemistry of (Dr. J. B. Harborne), 1051
 Plant Roots : Mechanism of Uptake of Trace Elements by (G. Findenegg and Prof. E. Broda), 196
 Plant Tumour Virus in Arthropod Host : Microcrystal Formation. (E. Shikata and Dr. K. Maramorosch), 507
 Plant Viruses : Antiviral Action of Oxidized Spermine-Inactivation of (U. Bachrach *et al.*), 1095
 Plants : Influence of Hexadecane on Absorption of Carbon Dioxide by (Prof. J. M. Riedhart), 300
 Occurrence of Fructo-e-l-phosphate in Tissues of Higher (D. Graham and Dr. T. ap Rees), 88
 Origin of the Geoelectric Effect in (Prof. M. B. Wilkins and A. E. R. Woodcock), 990
 Photosynthetic Mechanisms of Green, review by Dr. E. A. C. MacRobbie, 212
 Physiological Basis of Salt Tolerance in (Dr. B. P. Stroganov), review by Dr. P. A. Thompson, 211
 Shade Tolerance in Flowering (Dr. J. P. Grime), 161
 Some Postulated Relationships among Autumn Phenomena in Woody (R. B. Van Huyssee *et al.*), 89
 Uptake by, of Radiostromium from Contaminated Soils (A. J. Andersen), 195
 Plants at Sub-atmospheric Oxygen-levels : Effects of Oxygen Pressure and Salts on Germination of Winter Rye : Experimentation with (Dr. S. M. Siegel, O. Daly and C. Giunarro), 1012
 Plants of Europe : Vascular, Flora Europaea (edited by T. G. Tutin *et al.*), review by Prof. J. A. Nanfeldt, 8
 Plaque-formation by Non-immune and X-irradiated Lymphoid Cells on Monolayers of Mouse Embryo Cells (G. Moller and E. Moller), 260
 Plaque Size of Western Equine Encephalitis Virus : Influence of Heavy Water (Deuterium Oxide) on (R. I. Carp and Dr. D. Kritchewsky), 93
 Plasma Cholinesterase : Proposed Physiological Function for (H. S. Funnell and Prof. W. T. Oliver), 689
 Plasma Co-factors in Adenosine Diphosphate-induced Aggregation of Human Platelets (Dr. D. Deykin, C. R. Pritzker and E. M. Scolnick), 296

- Plasma Diagnostics with Microwaves (Dr. M. A. Heald and C. B. Wharton), review by A. E. Dangor, 965
- Plasma - Experimental Observations on the Structure of Collisionless Shock Waves in a Magnetized (Dr. J. W. M. Paul et al.), 133
- Plasma Globulins : Formation of Complexes between Basic Proteins of Leucocytes and (Dr. W. B. Jolley and H. W. Allen), 390
- Plasma Growth-hormone Levels in Chronic Starvation in Man (Dr. V. Marks, N. Howorth and F. C. Greenwood), 686
- Plasma Instabilities in a Dipole Magnetic Field : Laboratory Observations of (Prof. R. G. Quinn), 376
- Plasma Interaction Problems : A Wave Mechanical Approach to the (Prof. V. C. Liu), 883
- Plasma : Mechanism of Intestinal Absorption : Transport of Methionine and Sodium Butyrate by Intracellular (S. L. Hart and Dr. J. A. Nissim), 145
- Plasma of the Positive Column on some External and Internal Parameters : Dependence of the Properties of Moving Striations in the (G. Lakatos and Dr. J. Bitó), 445
- Plasminogen Activator by the Isolated Perfused Dog Kidney . Release of (Dr. R. Hølemans et al.), 291
- Plasmodium berghiei* in Different Experimental Hosts : Primary Tissue Phase of (Prof. M. Yoeli et al.), 903
- Plasmodium berghiei*, Vincke and Lips, 1948 : Mepacrine- and Primaquine-resistant Strains of (Dr. W. Peters), 693
- Plasmodium knowlesi* : Immunity to Malaria : Antigenic Variation in Chronic Infections of (Dr. K. N. Brown and I. N. Brown), 1286
- Plasmodium vinckei* . Gametogenesis of (Dr. J. Bafort et al.), 1230
- Plate and Shell Theory : Introduction to (C. E. Turner), review by Prof. B. N. Cole, 1137
- Platelets : Plasma Co-factors in Adenosine Diphosphate-induced Aggregation of Human (Dr. D. Deykin et al.), 296
- Platinized Platinum and Palladized Palladium Cathodes : Diffusion or Hydride Component of Hydrogen Overpotential at (M. N. Hull and Dr. F. A. Lewis), 887
- Platinum(II) $C_{10}H_{16}O_4PtCl_2$: Structure of a Diolefin Complex of (D. Gibson et al.), 580
- Platinum and Palladized Palladium Cathodes : Diffusion or Hydride Component of Hydrogen Overpotential at Platinized (M. N. Hull and Dr. F. A. Lewis), 887

Pye precision d.c. amplifiers

The Pye d.c. Amplifier, Cat. No. 11370, continuously monitors small voltage signals, such as those produced by many forms of transducer or detects the null point in various types of electrical measuring circuits and bridge networks. Its advantages are its freedom from vibration effects, constant response independent of bridge and circuit resistance and its capability to withstand overloads by virtue of the natural saturation of its actual amplifying circuit. Employing a contact modulator and special filter circuits it has been designed to operate without either input terminal grounded under all normal operating conditions. Its panel meter is scaled $100\mu\text{V}$ - 0 - $100\mu\text{V}$ in divisions of $2\mu\text{V}$ and range multipliers of $\times 1$, $\times 10$, $\times 100$ and $\times 1000$ are provided. Its gain is exceptionally stable and zero drift is less than $1\mu\text{V}$ per day. Response time of the panel meter is less than 1 second. Input resistance is 3500 ohms. An output of $\pm 10\text{V}$ at currents up to 5mA is provided for continuous recording and controlling. Primarily developed for the technologist this instrument is being used increasingly by research workers who require maximum stability and reliability.

W. G. Pye & Co. Ltd., P.O. Box 60, York St., Cambridge
Tel: Cambridge 58866 Grams: Pye Cambridge Telex: 81215

Pye is an acknowledged leader in the design of electronic measuring instruments which have faultless performance and exceptional reliability. In addition to various specialised d.c. amplifiers for chromatography, which measure currents as low as $1 \times 10^{-12}\text{A}$, are the null detectors/amplifiers listed below. Please write for details outlining your requirements.

d.c. Amplifier & Microvoltmeter, Cat. No. 11340/S.

A unique system of amplification which employs an oil-damped taut-suspension galvanometer modulator. Meter scaled $10\mu\text{V}$ - 0 - $10\mu\text{V}$ with range multipliers of $\times 1$, $\times 10$, $\times 100$, $\times 1000$. Input resistance is 50 ohms. Very low drift rate and noise level. Output 1mA f.s.d.

d.c. Nanoammeter, Cat. No. 11360.

A dual-purpose instrument similar to 11340/S but with ranges of $10\mu\text{V}$ - 0 - $10\mu\text{V}$ and $0.01\mu\text{A}$ - 0 - $0.01\mu\text{A}$ with multipliers of $\times 1$, $\times 10$, $\times 100$, $\times 1000$ on voltage and current. Very low drift rate and noise level 10^{-17} watts. Input resistance 1000 ohms. Output 1mA f.s.d.

Galvanometer Preamplifier, Cat. No. 11330.

Designed for fast response, highly sensitive null detection in d.c. bridge and potentiometer circuits. This robust, oil damped instrument gives an amplification of about 125 times the input current. Sensitivity with Scalamp Galvanometer, Cat. No. 7903/S, approx. $10000\text{mm}/\mu\text{A}$.

INDUSTRIAL RESEARCH AND THE RESEARCH ASSOCIATIONS

LAST February, in his Jubilee Memorial Lecture to the Society of Chemical Industry on the organization of basic research for the British chemical industry, Prof. J. W. Mitchell made some passing reference to the research associations, as well as to sponsored research and to the research institutes as supplementing the research effort within industry itself. The last two, he suggested, had four important functions: first, they could bring firms together in a joint project of mutual interest, though possibly not of immediate commercial significance, and probably at a smaller investment than would be required if the firms undertook it individually. This is obviously something in the nature of a small and temporary research association.

Next, they can supplement the firm's own industrial research effort at a time of crisis by undertaking sponsored confidential work. This represents in effect a temporary expansion of the firm's own research laboratories. Thirdly, Prof. Mitchell envisages such institutes as undertaking unsponsored basic research to acquire new knowledge of value to the industry as a whole, this function representing rather that of a central laboratory and perhaps more particularly the type of basic research in which some research associations seek to engage. Fourthly, he places the educational function arising out of the opportunities provided for graduates to extend their experience in research.

Prof. Mitchell's comments on the critical size of a research laboratory, which have previously been discussed (*Nature*, 207, 113; 1965), are highly pertinent here, as they are also in relation to his much briefer remarks on the work of research associations. The inability of most of the smaller firms to provide the financial resources required to establish laboratories of at least this critical size is one of the fundamental reasons for establishing a research association. Moreover, contrary to the customary protestation of the smaller firm, it is to them rather than to the larger firms of the industry that the benefits of co-operative research mainly accrue. Prof. Mitchell does not believe that sufficient basic research is as yet being undertaken in Britain to meet the needs of the medium-sized and smaller firms. Instead, he suggests that the more successful research associations have worked to improve services provided essentially on a non-competitive basis and have also undertaken research on improving and characterizing well-established products and developing equipment for standardization and control. He recognizes that difficulties arise over the granting of rights for developing and manufacturing new products based on discoveries or inventions made by a research association, but he does not refer to the inherent advantage that the industrial research laboratory inside a firm necessarily possesses over one outside through the closer contact with the production side or the customers' needs.

About the same time as Prof. Mitchell's lecture was delivered, the Association of Scientific Workers submitted to the Ministry of Technology a memorandum on industrial research associations. In this memorandum the Association argues that research associations should be a principal means for putting ideas across to industry and for making a scientific and technological impact on the industries served by the associations. A research association, it suggests, would serve its industrial members best if it consistently looked to the future, and to a fairly long-

term future. The associations should also accept a considerable responsibility for disseminating information, particularly to the smaller firms which are less likely to spend money and effort on an internal information service. This function is regarded as including the use by management of the information already available.

The memorandum admits that there are wide differences in the effectiveness with which different research associations fulfil their role, and these differences are attributed at least in part to the methods by which the research associations are financed—this affecting in turn the amount of money available. Recognizing also that industries which are lagging technically tend to lose interest in research and become even more backward, the memorandum suggests that amalgamation of appropriate research associations might give a firmer basis for development and that it would be worth while examining industries without co-operative research and co-ordinating the research efforts of companies undertaking substantial research in the same field. This latter somewhat naïve suggestion is not discussed further, but it is proposed that all research associations should operate within a national plan and be linked with the economic development council structure.

The present methods of finance are then criticized in some detail, especially for their failure to provide sufficient assurance of a reasonable level of income over a period of, say, five years: this is regarded as quite impossible if a research association has to depend on voluntary subscriptions. The position is made worse by the instability of prices and recurrent mergers and the like. The memorandum criticizes the progressive stiffening of grant terms by the Department of Scientific and Industrial Research, and it makes the valid point that too much effort has to be spent by directors of research in securing funds for research. Earmarked grants and civil research contracts are regarded as tending to increase financial strain and should not be looked on as a substitute for improved contributions from the Government to the regular programme.

As a consequence of this financial situation, the facilities for research in most associations compare poorly with those of Government stations. Total expenditure per qualified scientist and engineer in the research associations is put at much lower than the estimated average of £8,000 for all manufacturing industries in 1960; that for the research stations of the Department of Scientific and Industrial Research (now the Science Research Council) exceeds this figure. The consequent poor salary scales and prospects compared with the Scientific Civil Service make it difficult to attract and retain competent staff, and on the whole staff relations generally need improvement. The Association of Scientific Workers contends that an assured, adequate and independent income would immediately improve such relations. The unsatisfactory financial situation, of course, also hinders the acquisition of modern scientific equipment.

The system of finance is intimately linked with the method of control, and the memorandum maintains that the methods practised by the heads of businesses who dominate the Council of Research Associations are not always appropriate to the needs of technical departments. Moreover, financial and general control is largely a part-time interest of members of these Councils, leading to

haphazard and meretricious decisions, which may be based on narrow financial considerations. As a result, levels of expenditure may fall below the minimum necessary for efficiency and effectiveness, and voluntary levies agreed with the Board of Trade may not necessarily be fixed to ensure a sufficient level of expenditure. The memorandum also asserts that representations of the Department of Scientific and Industrial Research on the Councils and the Official Visitors are ineffective in influencing policy in proportion to the Government stake in the research associations.

Seven proposals are advanced in the memorandum to improve this position. First, a compulsory levy of 0.2 per cent of net output of the industries concerned is suggested in order to double the present total income of £10 million. Within this concept of a statutory levy, the Government contribution could be increased where necessary to pound for pound with the industrial contribution. Specifically, the appropriate Government agency should examine the need for establishing a research association, with a compulsory levy, for certain sections of the chemical industry. Possible amalgamations should be carefully considered and, in consultation with industry, the Minister of Technology should examine the programmes of all research associations. One function of the research associations should be to advise the Government in connexion with placing civil research and development contracts with industry. Establishment of an effective advisory service, using the most advanced techniques, is also recommended to ensure the dissemination of knowledge and techniques and their application to industry, and all research associations should participate in this service.

To some extent this last-mentioned recommendation anticipated the establishment of the Office of Scientific and Technological Information, but its effectiveness presupposes the existence within the small firm of those at the top capable of appreciating the significance of new knowledge and possessing the authority to take appropriate action. In most small-scale industry this condition is not fulfilled, and here, like so many other reports and memoranda, the memorandum is not sufficiently ruthless. There is too much disposition in Britain to protect the inefficient and it is this practice above all that must be ended. The research associations will never serve Britain effectively if they are used to feather bed the inefficient and backward.

Also early this year Dr. F. N. Woodward, scientific counsellor to the Organization for Economic Co-operation and Development, submitted to the Organization a survey of the different types of research association in member countries with particular reference to their organization, co-ordination, methods of operation and resultant benefit to the industries they serve. This report has now been published under the title *Structure of Industrial Research Associations**, but, although at some points the report supports some of the recommendations of the Association of Scientific Workers, there is such wide variation in the extent and character of Government participation from country to country that generalization is extremely difficult. Very little light is, in fact, thrown on the deeper aspects of co-operative research and the conditions in which it functions most successfully. By and large, the survey adds surprisingly little to the assessment of the research association movement in Britain contained in a series of articles in *Research* and since published as a

supplement to Volume 15 in 1962, or even, for that matter, to Prof. R. S. Edwards's earlier book, *Co-operative Industrial Research*, or the report of the Federation of British Industries on *Industrial Research in Manufacturing Industry, 1959-60*.

The factual data in Dr. Woodward's report show that the industrial research association has developed to a much larger extent in the United Kingdom than elsewhere in Western Europe: the income in Britain of some £10 million in 1962 was more than double that in Germany, which comes next, though it is less than that expended in France on the rather different industrial research centres, which amounted to some £16.7 million in 1961. The idea, moreover, differs significantly in structure and working philosophy from country to country, and its development from the British prototype has been influenced to a marked degree by historical background and local requirements. None the less, the disadvantages and shortcomings of the research association scheme, as revealed by Dr. Woodward's enquiry, coincide with observations in the memorandum from the Association of Scientific Workers. This is notably so in the criticism of the excessive proportion of time which a director of research is required to spend on raising money, of the slender resources of most of the associations and their inherent disadvantage as against the industrial research laboratory of a private firm.

In addition, the research associations in general are regarded as not possessing a good public image either in the industries which they serve or in the scientific world from which they must attract their staff. This is unlikely to be assisted by the development of contract research. It is at this point that there is need for more fundamental and independent thinking about the precise functions of the research associations even in those fields in which co-operative effort, so far from being at a disadvantage compared with private enterprise, is the most economic as well as the most potentially fruitful method. It should be recognized that while a certain minimum scale of effort is essential, that scale should not be secured by the use of public money to support the inefficient or reluctant, and that there are circumstances in which a Government research station may be a more effective and prudent answer than an amalgamation of research associations or a solution involving the coercion of reluctant firms. There is warning enough of the dangers of precipitate action in Dr. Woodward's survey to suggest a cautious approach to some at least of the proposals of the Association of Scientific Workers. Certainly, the hard thinking and further enquiry necessary as to the merits of private or public enterprise should be kept free from any party political prejudice.

CHEMISTRY OF THE SMALLER ORGANIC HETEROCYCLIC SYSTEMS

Heterocyclic Compounds with Three- and Four-membered Rings

Edited by Arnold Weissberger. Part 1: Pp. xi+1-646. Part 2: Pp. xii+647-1174. (The Chemistry of Heterocyclic Compounds: a Series of Monographs, Vol. 19, Parts 1 and 2.) (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1964.) 488s. the two parts.

THESE two books, each separately bound and of considerable size, form Parts 1 and 2 of Volume 19 in the series *The Chemistry of Heterocyclic Compounds*

* *Structure of Industrial Research Associations*. By F. N. Woodward. Pp. 55. (Paris: Organization for Economic Co-operation and Development, London: H.M.S.O., 1965.)

which, under the able editorship of Dr. A. Weissberger, have been appearing steadily and (in general) with increasing size since 1950. Some of the more recent volumes have appeared in two or more parts, and the number of actual books in the series is now twenty-five.

Part 1 deals with four types of three-membered ring systems and Part 2 with six types of four-membered systems: the pages of the two Parts are numbered as one volume, and Part 2 has an author and a subject index covering both Parts.

In view of the number of volumes which have preceded Volume 19, it might cause some surprise that these smaller and simpler systems have hitherto escaped attention in this series. Dr. Weissberger in the preface points out that heterocyclic chemistry has two closely related aspects, namely, the investigation of different derivatives of the respective cyclic systems, and that of the reactions in which the heterocyclic systems themselves undergo change. The latter aspect, he notes, is particularly important with heterocyclic systems having less than five atoms in the ring, some of which belong to the most reactive compounds in organic chemistry. This high reactivity undoubtedly underlies the recent wide extension of the study and the technical application of most of these compounds: it also probably explains the comparative slowness of earlier development, for less reactive and more stable systems attracted greater attention.

The contents of the two Parts can be briefly indicated. Part 1 contains chapters devoted individually to the systems listed as ethylene oxides (I); aziridines (II);

ethylene sulphides (III) and oxaziranes (IV). Part 2 contains the systems thietanes (V); β -lactones (VI), trimethyleneimines (VII), and a brief note on β -sultones (VIII A) and 1,2-oxazetene (VIII B), and finally oxetanes (IX).

An interesting point of nomenclature arises here. The International Union of Pure and Applied Chemistry (IUPAC) has recommended specific names for almost all heterocyclic systems up to the 10-membered units, and these names are now incorporated in the recent second edition of the *Ring Index* and its two supplementary volumes. Some of these names are far from self-explanatory and differ markedly from the older accepted names. It is interesting to note the extent to which they are accepted and used by the authors of Parts 1 and 2.

Dr. André Rosowsky entitles Chapter 1, on the compounds having the reduced system (I), "Ethylene Oxides", and points out that the IUPAC name is 'oxirane', and states: "in deference to common usage the present chapter will retain the terms 'apoxide' and 'ethylene oxide'". Dr. Fanta in Chapter 2 uses the systematic name 'aziridines' for compounds having the reduced system (II). Dr. Reynolds and Dr. Fields (Chapter 3) give the title "Ethylene Sulphides" to compounds having the system (III) and state: "The name thiirane is in accord with good nomenclature, but it has been slow to find a place in the literature". Dr. Emmons adopts the systematic name 'oxaziranes' throughout Chapter 4 for compounds having the system (IV). Dr. Etienne and his collaborators in Chapter 5 use the term 'thietane' for compounds having the reduced ring (V), but abandon it for the corresponding sulphonium salts (p. 650). Chapter 6 he entitles " β -Lactones", and states: "Nor does the (systematic) designation 2-oxetanone . . . seem to have been adopted". Dr. Moore gives the name "Trimethyleneimines" for Chapter 7 on compounds having the reduced

system (VII), but in the text refers to them throughout as "azetidines". Systematic names are used for the remaining three systems. This summary will indicate the degree of confusion which still exists in the nomenclature in use for even simple heterocyclic systems.

These two books contain such a wealth of information that a true review, in the sense of a critical assessment of the merits and demerits of the work presented, cannot be briefly achieved. The general nature of the treatment of each class, and of the information presented, can best be shown by reference to Dr. Rosowsky's excellent exposition of the ethylene oxides in Chapter 1, which, running to 523 pages finishing with 2,040 references, is almost a book in itself. It contains the sections: (1) "Physical Properties" (that is, molecular geometry; energetics; infra-red, ultra-violet and nuclear magnetic spectroscopy; theoretical models); (2) "Occurrence of Epoxides in Nature"; (3) "Synthesis of Epoxides"; (4) "Chemical Reactions of Epoxides"; (5) "Analytical Methods"; (6) "References": sections (3) and (4) are presented in considerable detail. This chapter incidentally reveals the contribution made by the French chemists, from the early work of Wurtz to the later work of Tiffeneau and others.

The remaining chapters follow much the same pattern, and the complete volume forms a very thorough and highly valuable record of chemistry of these smaller ring systems.

It is noteworthy that the synthesis of oxaziranes (Chapter 4) was first achieved in 1956-57 by three different research groups, and that in Chapter 8 only one example of a 1,2-oxazetidine, prepared by Staudinger and Jelagen in 1911, can be recorded. Our knowledge of the chemistry of such systems must still be incomplete.

One might perhaps question the space devoted in Chapter 3 to the "Table of Physical Properties" (6½ pages), for only the boiling (or melting) points are recorded for certain compounds: similarly in Chapter 6, Table 2 (18 pages) and Table 3 (10 pages) giving the physical properties of aliphatic and aromatic β -lactones, respectively, also provide very limited information, and certain pages of the Table contain only three of the more complex derivatives. The sections in this Chapter on the preparation of β -lactones have been largely anticipated by the recent Volume 7, Part 2, of *Methoden der Organischen Chemie*, by Houben-Weyl (*Nature*, 204, 1122; 1964): the latter is, however, strictly limited to synthetic methods, whereas Chapter 6 of the present work gives a full treatment of the whole subject.

It should be mentioned that the preface concludes with an expression of deep gratitude from Dr. Etienne and his colleagues for the faultless translation of their Chapters 5 and 6 from the French by the late Mrs. Weissberger, to whose help in his life and work Dr. Weissberger pays an eloquent and moving tribute.

F. G. MANN

ANALYTICAL CHEMISTRY

Organic Complexing Reagents

Structure, Behavior, and Application to Inorganic Analysis. By D. D. Perrin. (Chemical Analysis: a Series of Monographs on Analytical Chemistry and Its Applications, Vol. 18.) Pp. xi + 335. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, Inc., 1964.) 90s.

THE doyen of analytical chemistry, Fritz Feigl, has remarked that the story of modern analytical chemistry is the story of co-ordination chemistry. This remark has made a profound impression on many a young research worker, as has S. E. Q. Ashley's more recent comment that the chemistry is going out of analytical chemistry. These observations apparently point in two directions, but in truth they do not really conflict. While

an ever-increasing proportion of analyses is being carried out instrumentally rather than by balance, beaker and burette, the instrumental hardware, except in a few cases such as mass spectrometry, relies on chemical reactions. These reactions are largely based on complexation and are usually further backed up by refined modern separation techniques which again rely almost exclusively on complexation. The comments may, therefore, be regarded as complementary.

Complex formation between aquo-metal ion complexes and neutral or negatively charged ligands extensively modifies the normal (aqueous) chemical reactions of most ions and many characteristic physical properties usually associated with them. Thus many metal ions become central in anionic complexes and hence respond differently to sorption processes such as ion exchange and ion association reactions. Many become bound in uncharged complexes and precipitate from solution or can be persuaded to partition preferentially into water immiscible solvents. Some even become capable of being volatilized or distilled. In most cases changes are brought about in absorption characteristics in one or more regions of the electromagnetic spectrum. Not infrequently unusual valency states are preferentially stabilized by complexation, and the changes in oxidation potential which accompany such reactions open out avenues of examination by electrochemical techniques. Complex formation even extends a profound influence on to flame plasma techniques such as atomic absorption spectroscopy and flame spectrophotometry. In these cases, the supply of cations bound as neutral chelate or ion-associated complexes and dissolved in organic solvents can give considerable enhancement of sensitivity by purely mechanical surface tension/viscosity effects and can produce new reactions due to shifts from (normal) endothermic to exothermic dissociation-decomposition mechanisms. Many interionic interferences in flame techniques are also simply eliminated by virtue of complex formation. Similarly many apparently intractable techniques can be profoundly indebted to complex formation for their success. Thus, radioactivation analysis relies heavily on the solvent extraction of chelate complexes from aqueous solution to achieve the separation-concentration processes on which the radiocounting procedures depend.

Most modern texts on analytical chemistry are, of course, concerned with instrumental analysis and are at pains to emphasize the basic physical chemistry, the physics and even the electronics underlying these procedures. Few of them pay much attention to the chemistry involved. *Organic Complexing Reagents* is concerned with just this facet and takes the same pains to set the scene behind the chemical reactions in terms of modern theories of inorganic chemistry. In my opinion it succeeds admirably in this and the result is stimulating and worthwhile. The only book which has previously been written on this topic is Feigl's *Specific, Selective and Sensitive Reactions*, and although the latter is now sixteen years old, it is still one of the most fascinating and important of all books on analytical chemistry. This new book is written from the same point of view of basic chemical reactivity and is the first real development since the original publication. Unquestionably this is an important book of unusual interest and should be found by most analytical chemists and by many others to be a sparkling jewel of chemical interest set against the grey background of instrumental methodology on the bookshelf. It is equally certain that it will bid fair to become one of the most thumbed volumes on the shelf because of the wide-ranging nature of its interests.

The text itself is well arranged. A short chapter on chemical bonding set in terms of valence bond, molecular orbital and ligand-field theory follows a brief introductory survey of the phenomena of complex formation between metal ions and organic ligands, and sets the scene for subsequent chapters. This treatment is concise and en-

tirely adequate for those who have had some experience of modern theories, but those who are not familiar with them may well have to supplement their knowledge by further reading from the recommended list of books in order to make full use of the discussions which follow in subsequent chapters. The stereochemical configuration and stability of metal complexes are considered in terms of polarizability and covalent character and the thermodynamic nature of the formation reaction, etc. Numerous examples of ligand-field effects are cited in the transition series. The effects of complexation on oxidation potential are discussed in relation to factors which determine the magnitude of these potentials, ligand-field stabilization energies and so on, with examples drawn chiefly from among iron and copper complexes and cyanide complexes in the transition series.

A résumé of factors which govern rates of formation and dissociation introduces a chapter of a more applied nature on the effects of complexation on the concentration of cations in aqueous media and which is, of course, principally concerned with compleximetric titration, with masking and with demasking. Surface phenomena associated with complex formation are related to analytical techniques such as ion-exchange, chromatography, use of adsorption indicators and, somewhat illogically in this context, polarography. The chapter on visible and ultraviolet absorption spectra includes some useful notes on types of spectra and considers re-emission phenomena in relation to fluorescence and chemiluminescence. It also incorporates an interesting survey of the design of ligands in relation to absorption spectrophotometry. The two chapters on the solubility of complexes and extraction into organic solvents give an excellent coverage of their subject-matter and relate gravimetric and separation procedures to the nature of the reagent reacting with the metal cation. The reaction of inorganic anions with organic reagents and with metal complexes is considered from a variety of angles in a short but thought-provoking section. The final three chapters deal with procedures for detecting and determining inorganic neutral molecules, the general analytical properties of the elements and with some speculative matter on seeking new organic reagents for use in inorganic analysis. The book ends with a full subject index; there is no author index.

This, to my mind, is one of the most important books to have been written on inorganic analytical chemistry within recent years.

T. S. WEST

SOLID-STATE PHYSICS

Solid State Physics

Advances in Research and Applications, Vol. 15. Edited by Frederick Seitz and David Turnbull. Pp. xvi + 505. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 118s.

THE series of volumes entitled *Solid State Physics* has come to be of considerable importance to solid-state physicists. For most people active in this field there are several articles, scattered through the volumes, to which they and their research students return again and again. The articles are, for the most part, closely written and demand quite intensive study if they are to yield a substantial portion of their content. Most will offer something to the generally informed physicist who reads quickly through them, but this is not their main function. One wonders in some cases whether this class of reader, and even the experts and prospective experts (not to mention reviewers), might be helped by a somewhat more emphatic distinction between the main points to be made in the article and subsidiary elaboration. The articles fall little short of small books, and a suitably discreet modification of the 'on a first reading' formula might not be inappropriate.

Volume 15 of the series resembles previous ones in being occupied mainly by essentially theoretical articles in which the properties of well-defined models are worked out and compared, more or less thoroughly, with experiment. The longest article, that by R. W. James on the "Dynamical Theory of X-Ray Diffraction", falls very clearly into this category. It will prove of great importance to workers in electron diffraction as well as to those concerned with X-rays. In treating the "Elementary Theory of the Optical Properties of Solids", F. Stern combines a discussion of phenomenological electromagnetic properties, including the wave-length dependent dielectric constant, with treatments of the free electron gas, electrons and holes in semiconductors and optical modes in ionic crystals: the application of dispersion relations is considered. L. J. Sham and J. M. Ziman discuss carefully the basic concepts of "Electron-Phonon Interaction" and the resulting electron scattering in solids. The considerations which they present resolve a number of questions and doubts on some fundamental points, and lead to clear definitions of the matrix elements which appear in the theory: topics treated include deformation potential, pseudopotential and screening effects. In discussing "Spin Temperature and Nuclear Relaxation in Solids", L. C. Hebel impresses one further with the rich interplay of theoretical and experimental activity (theorist and experimenter often being the same person), which has characterized work in nuclear magnetic resonance.

The first article in the volume, that by G. Borelius on "Changes in Energy Content, Volume, and Resistivity with Temperature in Simple Solids and Liquids", is in a different category. Here the experimental results dominate, and such theoretical discussion as there is frequently emphasizes the apparent inadequacies of present-day theory. It is good to see this approach represented.

C. W. McCOMBIE

SCHRÖDINGER'S LOGIC

My View of the World

By Erwin Schrodinger. Translated from the German by Cecily Hastings. Pp. viii + 110. (Cambridge: At the University Press, 1964.) 18s. net; 3.50 dollars.

THIS book consists of two long essays, hitherto unpublished. Although separated by a long period—the first was published in 1925, and the second in 1960—there are close links between them in respect of subject-matter and treatment. There are also affinities with the reflexions with which Schrodinger concluded his book *What is Life?* (1944), although this book is not mentioned in the present work.

In these pages Schrodinger puts forward a philosophical and indeed metaphysical view of the world, of human experience and of human nature. He rightly does not attempt to derive these conclusions from theories in the natural sciences but adopts a starting point which is philosophical—that is to say, one in which the sciences themselves are located in the wider context of human experience of the world and of moral relationships. Schrodinger accepts the validity of Kant's criticism of speculative metaphysics but argues, in my view correctly, that to some degree metaphysics, in the sense of pre-suppositions of enquiry, is indispensable. The particular problem which concerns him is the basic one of the relation between experience and reality. He points out that the commonsense view that independent observers, or 'selves', have similar experiences of the same external world is not self-authenticating; here Schrodinger is clearly under the influence of his mentors, Mach and Avenarius. There is no doubt that Schrödinger is right in saying that this is a metaphysical point of view in the sense explained. It is with less plausibility that he seeks to supplant it with an alternative and indeed inverted metaphysical doctrine which he derives from the Vedanta.

Instead of thinking of different selves experiencing a common world, he invites us to think of a multiplicity of selves sharing a common consciousness. According to this idea there is no ultimate distinction between different minds or indeed between consciousness and its object. To a Westerner, at any event, this is a paradoxical view which lacks inherent plausibility; unfortunately Schrodinger does not offer convincing arguments in its support.

Another difficulty is that Schrödinger appears to think that it goes some way to solving a problem the genuineness of which is very much open to doubt. "If she who is now your mother had cohabited with someone else and had a son by him, and your father had done likewise, would you have come to be? Or were you living in them, and in your father's father . . . thousands of years ago? And even if this is so, why are you not your brother, why is your brother not you, why are you not one of your distant cousins?" To ponder why I am not my brother, or where or what I would be if my parents had not met, is to induce a kind of intellectual vertigo for which the cure is not the Vedanta, but rather a closer attention to the logic of our language. The reason why I am I and not someone else, or that this pencil is this pencil and not another pencil, is to be found in the logical principle of identity—that is, a tautology. Schrodinger is not the first, and will not be the last, to find in logic a source of wonderment, and in metaphysics an apparent resolution of it—but what precisely is the 'problem', as distinct from the wondering?

C. K. GRANT

SPECTROSCOPIST'S VADE-MECUM

Flame Spectroscopy

By Radu Mavrodineanu and Henri Boiteux. (Wiley Series in Pure and Applied Spectroscopy.) Pp. xiv + 721. (New York and London: John Wiley and Sons, Inc., 1965.) 315s.

FLAME Spectroscopy, by Drs. R. Mavrodineanu and H. Boiteux, is probably one of the most detailed and comprehensive works on flame emission spectroscopy and atomic absorption spectrophotometry which has ever been written. It may be regarded as a modernized edition of the original *L'Analyse Spectrale Quantitative par la Flamme*, published in France in 1954.

The authors deliberately avoid the discussion of practical laboratory methods for the analysis of specific elements or compounds, although most extensive references are given to published papers of this type.

The present publication has a far more generic approach to the theoretical and instrumental aspects of flame spectroscopy, the descriptive text being embellished with photographic illustrations and diagrammatic representations of the highest quality and most commendable clarity. The coverage given to spectrographic instrumentation is truly international, the products of the world's most well-known instrument makers being given detailed attention. The construction, performance and general physical parameters of these spectrometers, etc., are concisely listed for rapid comparative reference.

The present work is presented in three parts comprising twenty-two chapters. The first part deals in a most exhaustive fashion with the fundamental principles of flame production; inflammability, burning velocity, temperature contours, etc., are but a few of the topics lucidly described. In addition to the less common flames of cyanogen-oxygen or hydrogen-perchloryl fluoride, much attention is directed to plasma jet, atomic hydrogen and high-frequency flame systems.

Numerous types of burners and atomizers are clearly described, the range covered extending from the apparatus of Beckman (1899) and Lundegårdh (1936) to the ultrasonic device of Peskin and Raco (1963). Much valuable detail is also given regarding the properties of materials

suitable for the construction of these flame spectroscopic accessories.

Sensing elements of the photographic plate and photo-sensitive type receive detailed treatment. Interfering phenomena are listed; the advantages of the absorption method for resonance radiation investigations is noted and many allied topics of vital spectroscopic interest are clearly presented. Part 2 deals with the fundamental theoretical treatment of atomic and molecular spectroscopy; modern ideas of atomic structure are related to values of emission frequencies. Parity, selection rules, coupling, isoelectronic sequences and hyperfine structure are just some of the numerous topics discussed. The band spectra of molecules receive similar detailed treatment.

Subsequent chapters contain extensive data from spectral examinations of atoms and molecules excited in acetylene flames. The wave-length tables are accompanied by photographic reproductions of typical spectra and provide a reference work of the greatest value and utility to the practising analyst.

The publication may appear expensive (315s.) but it is a massive, well-produced work of the greatest value and authority. It will provide a powerful teaching and experimental aid and contains much that is new and scientifically helpful. Since it must prove a well-thumbed vade-mecum, the publishers have thoughtfully provided a durable additional cover-case which will help to protect it from the buffetings of constant use. D. T. LEWIS

THE CHROMAFFIN CELL

The Natural History of the Chromaffin Cell

By Prof. Rex E. Coupland. Pp. xi+279. (London: Longmans, Green and Co., Ltd., 1965.) 50s. net.

EVER since Vulpian in 1856 noticed that sections or extracts of the adrenal medulla could produce colours on oxidation, the significance of chromaffin tissue and the adrenal medulla in particular has interested a great number of investigators. So important did the adrenal medulla appear to be that for a time the vital functions of the adrenal cortex were completely ignored. Interest appears to have declined in recent years due to the counter-attractions of the postganglionic sympathetic nerve-endings.

The Natural History of the Chromaffin Cell has appeared at a most opportune moment to describe what has already been achieved and to point out the possibilities for further useful work on the study of the chromaffin cell. Until now it has been very difficult to obtain an overall picture of the published work on this subject since so many different specialists have been involved. Prof. Coupland has succeeded in combining the anatomical, histological and physiological data in a way that makes this book a fine reference source and at the same time a pleasure to read. He restricts his scope to a consideration of the chromaffin cell defined as "an element developed from the neuro-ectoderm, innervated by pre-ganglionic sympathetic nerve fibres capable of synthesizing and secreting catecholamines and storing them in sufficient quantities to give a positive chromaffin reaction with aqueous solutions of potassium dichromate or chromate". This, of course, excludes the enterochromaffin cells, mast cells and dopamine-storing cells. Without these a coherent account is possible. To include them would only confuse the story.

The first chapter is concerned with the histology, histochemistry and ultrastructure in which the various methods of preparation and staining are critically evaluated. Emphasis is placed on the histochemical methods available for the visualization of the catecholamines, but staining techniques for other cell constituents are also included, together with a section on the electron microscopy of chromaffin tissue. The embryological and foetal

development is then described in which the evidence bearing on the origin of the chromaffin cells from the neuroectoderm is explored, including the recent evidence that some of the cells may arise from the neural tube. The chapter on the post-natal fate of the extra-medullary chromaffin tissue gives Prof. Coupland a chance to point out the problems associated with the use of human material and also to describe his own work in some detail. He also fully reviews the literature available on the innervation and blood supply to chromaffin tissue. In the chapter on the synthesis, storage and secretion of catecholamines, a fair balance is maintained between the apparently conflicting evidence concerning the actions of reserpine on the innervated and denervated adrenal gland. A whole book could be written about the metabolism of catecholamines; the author does well to cover the subject within a reasonable space without the chapter degenerating into a list of references. The chapter concerned with functions of chromaffin cells in the body also, surprisingly, contains a section on the metabolic fate of the released catecholamines. There is a brief survey of the occurrence and characteristics of tumours of chromaffin tissue. The book ends with a chapter on the comparative anatomy of chromaffin tissue throughout the many orders of vertebrates and invertebrates. These final two chapters must be included for the book to be complete and will serve to widen the knowledge of many.

At the end of each chapter there is a comprehensive list of references with titles. This removes the need for the numbering of references and cross-indexing, but an author index would have been useful. The subject index is adequate for a book of this size. There is the usual quota of minor misprints which detract little from the overall quality of the book, and even *N-methylnoradrenaline* is readily translated as *N-methyladrenaline* by a quick look at the list of references.

Prof. Coupland is to be congratulated on the excellence of this monograph and the publishers for the quality of production at, for these times, a reasonable price.

B. A. CALLINGHAM

TECHNIQUES IN CELL METABOLISM RESEARCH

Methods in Cell Physiology

Vol. 1. Edited by David M. Prescott. Pp. xiii+465. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1964.) 118s.

ALTHOUGH much of the progress and orientation of modern biochemical research on cell metabolism and its control has derived from investigations on bacteria, there are many problems relating to the regulation of cellular processes for the study of which larger unicellular organisms are more suitable. Such are the control of mitosis, nucleolar function, nuclear-cytoplasmic relationships, and pinocytosis, as well as problems relating to the control of special forms of differentiation, such as encystment. When cells are large enough to permit microsurgery, such as the transplantation of nuclei, or when synchronous mitosis or synchronous encystment can be induced, the opportunities for investigating cell regulation at a genetic or a biochemical level are enormously improved. Although various organisms with these properties are known, and have been extensively studied in the laboratory, many research workers who might feel inclined to use them for their own purposes, but are not already familiar with them, are liable to be put off trying to do so because the techniques for handling such organisms are unfamiliar and their difficulty hard to evaluate. With Volume 1 of *Methods in Cell Physiology* in their hands such doubts and hesitations should vanish.

This excellent volume contains a series of chapters devoted to the techniques for growing and handling cells

of different kinds, with discussion of their advantages and limitations for particular purposes. Each chapter is written from extensive practical experience, and gives details not only of how to grow these cells but also, where necessary, of how to stain them and how to make the special tools for handling them, such as those required for microsurgery. Cells suitable for synchronous culture include *Chlorella*, *Acetabularia*, *Euglena*, *Tetrahymena*, and mitotic synchrony can be induced in *Physarum polycephalum* by coalescence of the microplasmidia. Cells suitable for microsurgery of various kinds are *Stentor*, *Amoeba* and *Euplotes*, and grasshopper neuroblasts. A separate chapter is devoted to methods for studying pinocytosis, especially in amoebae.

There are also five useful chapters on autoradiography which alone would make this volume worth purchasing. These also are full of practical details for obtaining the best results in quantitative autoradiography, high-resolution autoradiography, and autoradiography of water-soluble materials and of mammalian chromosomes. A most valuable feature is the discussion of the theoretical and the practical limitations of the techniques advocated. Finally—and appropriately—J. E. Edström contributes a chapter on micro-extraction and micro-electrophoresis for determining and analysing nucleic acids in isolated cells which makes even this *tour de force* seem possible for other mortals. The editor, D. M. Prescott, is to be congratulated on the production of a thoroughly useful volume.

J. H. HUMPHREY

SURGERY AND SCIENCE

The Surgeon's Craft

By Prof. Hedley Atkins. Pp. x+201. (Manchester: Manchester University Press, 1965.) 15s. net.

THIS readable little book traces the development of the surgeon's craft from prehistoric times to the present day and is presented in a form readily understandable by the non-medical reader. It should therefore appeal to scientists engaged in the physical, chemical and biological sciences on which surgery has so extensively drawn to make many of the achievements described possible. Here in short compass is recorded how surgeons operate on the heart and other vital organs with impunity; that these achievements are of comparatively recent origin is shown by the startling statement that well into the nineteenth century surgery was "bloody, brutal and dangerous"! Asepsis and anaesthesia were soon to alter that fearsome state of affairs. The distinction which the author draws between the surgeon and his more intellectually inclined physician colleague is probably fair, but he makes it clear that, especially in university departments of surgery and in the Royal Colleges, more and more younger men are undertaking basic research, both biochemical and biological, and thus bridging the gap between the laboratory and the wards and operating theatre.

The thorough, exacting and protracted training of the surgeon, and what kind of man he is, are described. This should give the non-medical scientist the chance of comparing this with his own training and attributes. Culmination for the surgeon is reached on appointment to a consultant post, usually in his late thirties, and no doubt the question as to why the surgical training takes so long will be asked. The answer would seem to be the immense responsibility in dealing with human patients, and this is reflected in the financial awards which will be of great interest to other scientists.

The author sees a glowing future for surgery, despite the ultimate object of surgery being the abolition of surgery. By the combined attack of many scientific disciplines it is to be hoped that a disease such as cancer will one day be conquered and so make the mutilating operations needed for its complete extirpation a thing of

the past. Truly then would the ultimate object of surgery be achieved. It is interesting to speculate what would be the effect on the surgeon's craft of the elimination of cancer, rheumatoid arthritis and cardiac and renal diseases. The solution of the homograft problem in transplantation would undoubtedly bring other outstanding problems into the surgical arena, and future advances must of necessity bring a profound change of outlook and approach for the surgeon.

Thus although *The Surgeon's Craft* still presents surgery in the main as a 'craft', the reliance of modern surgery on many scientific disciplines is obvious and should be a pointer to the training and occupation of the surgeon of the future. Prof. Atkins skilfully blends the clinical aspects of surgery with its scientific foundations. The proceeds of the sale of this book have been generously donated for the preservation of Down House as a memorial to Charles Darwin, from whom modern surgery drew much inspiration.

N. W. NISBET

PRINCIPLES APPLIED

Genetical Principles and Plant Breeding

By Prof. Watkin Williams. (Botanical Monographs, Vol. 5.) Pp. x+504. (Oxford: Blackwell Scientific Publications, 1964.) 70s.

THE title of this book suggests a similarity of content with several others written on the theme of plant breeding in recent years, but it differs from them in at least two important respects. First, it is directed towards a student audience, principally to those who are studying in the general sphere of agriculture, and secondly, it consistently relates the pure and applied aspects of genetics without burdening the text with either crop botany or the intricacies of the routine methods of crop improvement. It is tailor-made for course requirements and aims to provide an understanding of the genetical principles governing the lives of flowering plants, and of the methods which lead to their improvement.

The first five chapters deal with such basic considerations as the genetic components, the organization of the genes, the chromosome complement, mutation, and the role of the cytoplasm in heredity. Basic Mendelism and descriptions of mitosis and meiosis are not included as a knowledge of these is presumed. Genetic systems governing sex determination and breeding behaviour occupy three chapters with especial emphasis given to incompatibility systems. The following two chapters are concerned with plant populations, their adaptation to their environment, and the influence of selection. The genetic basis of disease resistance forms the subject of the penultimate chapter and, finally, there is a description of special techniques such as chromosome substitution and addition, the utilization of haploids and the production of polyploids. The text is liberally supplied with line drawings, tables and photographs and the bibliography is adequate.

Genetical Principles and Plant Breeding is attractively written with a degree of lucidity which will make it popular with many. It covers the broad subject adequately and with the authority which we may expect from Prof. Williams's wide experience of practical plant breeding and genetics. It is refreshing to see attention directed to chimeras and plastid mutation though equally it is disappointing that *Xenia* receives no mention.

Although this book seems remarkably free from factual errors, like others which have gone before, it perpetuates a few fallacies which are now in danger of becoming regarded as facts. For example, emphasis is placed on the incomplete meiotic pairing of autopolyploids with its detrimental effect on fertility, and the relative natural rarity of such plants is attributed to these causes. What is here overlooked is the complete pairing and high fertility of many autopolyploids and the ready response to selection, either natural or artificial, of those which are irregu-

lar. To then presume that infertility is the explanation for the lack of success of autopolyploids is to ignore the fact that many allopolyploids have also to overcome, and do, a barrier of sterility even more extreme than that of autos, albeit at the diploid level.

The success of this book will ultimately be judged by generations of students, but already it seems likely to be assured. The contribution which it makes can scarcely be said to startle or surprise, rather will it interest and satisfy, both the students for whom it is intended and others of more advanced levels of learning. K. JONES

VASCULAR PLANTS OF EUROPE

Flora Europaea

Edited by T. G. Tutin, V. H. Heywood, N. A. Burges, D. H. Valentine, S. M. Walters and D. A. Webb, with the assistance of P. W. Ball and A. O. Chater. Vol. 1: Lycopodiaceae to Plantanaceae. Pp. xxxii+464+5 maps. (Cambridge: At the University Press, 1964.) 84s.

THE publication of this volume (the first of four) means a most remarkable event to all biologists. To the layman and perhaps also to numerous biologists it may be a great surprise that no such work existed earlier. It is true that at the beginning of scientific botanical taxonomy the number of known species was so small that it was possible to publish works enumerating and describing them all. In his *Species Plantarum* (first ed., 1753), Linnaeus listed about 6,000 species in all, about 5,400 phanerogams and about 600 cryptogams. He believed the flora (and the fauna) of the tropics to be rather uniform and estimated the total number of plant species (of all groups) to be about 10,000. How wrong he was! The number grew rapidly and steadily through expeditions to various parts of the world. The microscope opened new worlds among the cryptogams. It became impossible to embrace the whole world in one *Flora*, and also other kinds of specialization became necessary. Besides phanerogamists (and pteridologists) there came bryologists, phycologists, mycologists and lichenologists. It has nowadays almost become a convention that a *Flora* without any specifying attribute means one treating only phanerogams or vascular plants (that is, phanerogams + pteridophytes). The *Flora Europaea* is no exception, for it is no complete *Flora* but one restricted to vascular plants.

Even the relatively poor phanerogamic flora of Europe exceeds numerically the 10,000 species which Linnaeus thought to represent the final and total sum of all plant species. The total number of known species of phanerogams alone is to-day judged to approach 250,000. Their final number cannot be estimated with any certainty as yet. In recent years the number of new species proposed seems to be on the decline, which may indicate that the stock of unknown species is now becoming exhausted. As to the European phanerogamic flora there remain certainly rather few species to be detected as new to science (or as new to Europe).

Why have we not had a comprehensive *Flora* of European vascular plants much earlier? The main reason is that floristic (and faunistic) studies have in the past mostly been restricted geographically by political or even provincial boundaries. A positive merit of such restricted areas is that the making of inventories can be more thorough and lead to relative completeness within reasonable time. But there are also negative merits. The limits of distribution of plants (and animals) do not follow administrative boundaries. Even where there has been no 'iron curtain' scientific contacts and field studies across the boundaries have been much too scarce, and so it may happen that the same plant is identified differently in different countries and, vice versa, that different species pass under the same name in different countries. Moreover, the full amplitude of intraspecific variation and the sterility bar-

riers of a species cannot be elucidated without following it throughout its whole area.

Most European countries possess *Floras* of their own, often modern and good ones. There are also *Floras* of a more regional character, for example, those treating two or more of the Nordic countries. The most pretentious *Synopsis der Mitteleuropäischen Flora*, started in 1896 by Ascherson and Graebner, has remained an unfinished work, but Hegi's magnificent *Illustrierte Flora von Mitteleuropa*, begun in 1908, runs now into its second edition. The eastern part of Europe is included in the gigantic *Flora URSS* (30 volumes, 1934-64).

In the 1940's the German W. Rothmaler projected a *Flora Europaea*, which was to cover not only Europe but also the Caucasus, Transjordan and the parts of North Africa with Mediterranean flora. Post-war-time conditions were, however, too unfavourable for the realization of his project. On British initiative the question was discussed at the eighth International Botanical Congress (Paris, 1954) and shortly afterwards a committee was formed in Britain with T. G. Tutin (Leicester) as the chairman and V. H. Heywood (Liverpool) as the secretary. With enthusiasm they went to work. They gained support from all parts of Europe and financial aid from various sources, especially the D.S.I.R. Editors for the different families, regional advisers for the different countries and contributors were appointed. It was soon realized that the inclusion of North Africa would mean a disproportionately large amount of work, and so Europe was taken in its traditional sense. It seems queer, however, that Novaya Zemlya is excluded.

The editors' intention has been to produce a concise and complete *Flora* in the shortest possible time instead of aiming at the solution of all problems by meticulous monographic studies. The first volume was ready in 1964, and it is planned to complete the *Flora* over the next eight years.

The first volume treats the pteridophytes, the gymnosperms and part of the dicotyledons (Salicales—part of Rosales). Among the larger families may be mentioned Caryophyllaceae, Ranunculaceae, Cruciferae and Saxifragaceae. The largest genera are *Silene* (166 species), *Ranunculus* (131 spp.), *Saxifraga* (123 spp.) and *Dianthus* (121 spp.). It follows from the aim of the work that the treatment cannot be uniform. This seems to be the case especially with the higher taxa. The delimitation of families and genera is sometimes hypermodern but mostly conservative; the generic concept is sometimes wide but mostly rather narrow. *Huperzia*, *Lepidotis* and *Diphasium* are thus segregated from *Lycopodium*, *Consolida* from *Delphinium*, *Hepatica* and *Pulsatilla* from *Anemone*, and *Jovibarba* from *Sempervivum*. The species concept is, on the whole, moderately narrow. Sub-species are included but as a rule not taxa of lower rank. In some cases rather local races (especially some from the British Isles) have been treated as sub-species; in numerous other cases such are discussed shortly without being given a definite taxonomic rank. The descriptions of the taxa of all ranks are clear and concise. There are keys not only to genera, species and sub-species but also to the families, which is a most unusual feature. I have not as yet tried to use the keys, but they look reliable. I have looked up all the Nordic plants and found no serious errors or omissions but a few debatable points and several interesting suggestions which deserve careful consideration. For less-known parts of Europe the volume contains a wealth of new information. In all parts of Europe it will certainly stimulate further research along different lines, as it gives an excellent review of the present state of our knowledge and makes the results of previous studies easily available. Last but not least, it will be the indispensable tool for everybody wishing to name a European plant from outside his own country. The next three volumes are eagerly awaited. All engaged in the project are to be congratulated on this first volume.

J. A. NANNFELDT

Modern Trends in Immunology, I

Edited by Prof. Robert Cruickshank. Pp. vii+263. (London: Butterworth and Co. (Publishers), Ltd., 1963.) 65s.

THE rapid developments in immunology to-day undoubtedly call for a 'modern trend' series to supplement the classical text-book treatment of the subject. The horizons of immunology are expanding all the more quickly because of the removal of barriers between different disciplines and the exchange of techniques.

This book is indeed a good start to a series of such modern trends. Although much of the basic knowledge is reviewed, for completeness, the modern views are put into perspective and recent technical developments are well covered. The chapters on immunity have nothing new to add when dealing with natural or acquired bacterial immunity and it is surprising to see so much space allotted to such text-book information. The chapters on acquired viral and protozoal immunity, however, bring the subject up to date. The chapter on immunization "follows a course more or less as empirical as the subject itself" (to quote the author), and it is unfortunate that the reporting of the part played by maternal antibody is not up to date. In this chapter there is much overlap with that on acquired bacterial immunity. Hypersensitivity is well presented and, as the author says, the different disciplines now engaged in this subject may well result in the resolution of many of the problems in the next few years. The chapters on auto-immunity and transplantation immunology are most informative and do much to bring the book into the modern trend. Here again it is noteworthy that the authors comment that "the fusion of transplantation with other immunological disciplines also involves a complementary process".

This book is most useful to the post-graduate student and we hope it is the first of an interesting and informative series.

F. T. PERKINS

Electrical Machinery and Control

By Prof. Irving L. Kosow. (Prentice-Hall Series in Engineering Technology.) Pp. xx+707. (Englewood Cliffs, N.J., and London: Prentice-Hall, Inc., 1964.) 94s.

ONE of the major difficulties that impose unnecessary restrictions for the control engineer designing a complex system is that the specialist designers of the components that go to make up the system are motivated by different criteria. Thus, the electrical machine designer is concerned with iron and copper losses and with stray load losses. While these are the keystones of good design for large power machines when used independently, they are of secondary importance to such factors as controllability, torque to inertia ratio and power gain when used as a component part of a control mechanism.

It is therefore with great expectation that one approaches a new work combining both control and machinery. The connexion is, however, never made; control is represented by a final short chapter on servo-mechanisms so elementary and trivial as to be useless. Not once in the whole 700 pages are the dynamic characteristics of machines mentioned. The steady-state approach is used throughout and so is of little use to the control engineer. The addition of the term 'Control' to the title of the book is thus misleading.

As a book on machine principles it is also very doubtful if it will arouse much interest. It is written in an elementary manner with no attempt at analysis and a lack of modern fundamental unifying concepts. As an example one could quote the treatment of the force on a conductor carrying current in a magnetic field. The simple law is quoted but there is no discussion on the physical implications. There is no treatment of current embedded in slots in iron and the distribution of forces on the iron, and little evidence for the student that in modern machines

the field around a conductor is negligible and that the tooth forces produce the drive.

It is also extremely naïve in its approach. After stating that synchronous induction motors are only made in smaller sizes, it says "Because of the salient pole rotor the motor pulls into synchronism quite easily . . .". This is not true; it is the difficulty of the synchronizing phenomenon (which is a transient dynamic problem and therefore ignored) which prevents large-scale machines of this type from being constructed.

Each chapter concludes with a number of problems and the answers given separately. A set of trigonometry tables is provided as an appendix.

Beryllium Oxide

Edited by R. Smith and J. P. Howe. (Proceedings of the First International Conference on Beryllium Oxide, Sydney, Australia, October 21-25, 1963.) (Reprinted from *Journal of Nuclear Materials*, 14, 1964.) Pp. 498. (Amsterdam: North-Holland Publishing Company, 1964.) 200s.

THE first International Conference on Beryllium Oxide, attended by scientists from six countries, was held at Sydney in October 1963. The conference was sponsored and organized by the Australian Atomic Energy Commission to review and discuss recent advances in knowledge of the behaviour of beryllium oxide, particularly from the point of view of its possible use in nuclear reactor systems, as a moderator material.

The present volume, which is reprinted from the *Journal of Nuclear Materials*, is a collection of the fifty-five papers presented at that Conference, together with an account of the discussion which they provided. The papers are divided into seven sections. These deal with: (i) utilization of beryllium oxide in nuclear reactors; (ii) radiation effects in beryllium oxide; (iii) structure and physical properties of beryllium oxide; (iv) sinterability and sintering of beryllium oxide powders; (v) fabrication and mechanical properties of beryllium oxide; (vi) corrosion of beryllium oxide by water vapour; (vii) beryllium oxide-based dispersion fuels.

The book is attractively produced.

M. F. LAPPERT

European Brewery Convention

Report of the Barley Committee: Trials, 1963. Pp. 184. (London: The Institute of Brewing, 1965.) 15s.

THIS consists very largely of tabulated results of growth and malting trials of about twelve comparatively new hybrid barley varieties in fifteen Western European countries. The data, mostly arranged country by country but with a broad introductory survey, cover a much wider range than might be anticipated. Thus, they include summaries of trial lay-out, field observations, meteorological conditions as well as the crops themselves and their analytical examination. The objects behind this massive effort are not specifically or solely concerned with those qualities, such as disease resistance, yield, earliness in ripening and production of straw, which might first come to mind. These considerations are all economically important but are in the present context secondary to the main one of malting quality. It is clearly unlikely that any one variety will be equally desirable under a wide range of climatic and agricultural conditions. The continuing experience afforded by these trials, nevertheless, must be generally valuable, not least in respect of the economic conditions brought about by the European Common Market. The scientific value of this *Report*, however, encompasses more than the results themselves or the clear way they are presented; it presents what is probably a unique picture of the inevitable complexity involved in selecting improved varieties of even a single crop when many slight or scarcely appreciated variables may be brought into play.

RADIO OBSERVATIONS OF SPIRAL GALAXIES

By PROF. B. Y. MILLS, F.R.S., and J. R. GLANFIELD

Cornell-Sydney University Astronomy Centre,
University of Sydney

AN opportunity to investigate some of the brighter southern galaxies has been afforded by the recent completion of the east-west arm of the cross-type radio telescope at the Molonglo Radio Observatory¹. While a thoroughgoing investigation requires the resolution of the whole instrument, it is found that the east-west arm alone, operating as a simple total power radiometer, provides quite useful information. It has a beam-width measuring 1.5' E.-W. by 4° N.-S. at a frequency of 408 Mc/s and is limited in sensitivity by confusion effects at a flux density of about 0.5–1 flux unit (10^{-26} W m⁻² (c/s)⁻¹). Several observational programmes are being carried out while work proceeds on the completion of the north-south arm.

We here report observations of the three brightest southern spiral galaxies, *NGC 253*, *NGC 4945* and *NGC 5236*. These were first observed by Mills at a frequency of 85 Mc/s with a beam-width of 49' arc². It appeared that their integrated emission is very similar to spiral galaxies observed in the northern hemisphere by Hanbury Brown and Hazard³, but the resolution was not adequate to resolve the galaxies and examine their structure. More recent observations by Mathewson and Rome⁴ gave surprising results. Using the Parkes 210-ft. reflector at a frequency of 1,410 Mc/s, at which the beam-width is 14' arc, they found that none of the foregoing galaxies was resolved, although their optical sizes are such that a clearly visible widening of the radio telescope response was expected. They concluded that the model of radio emission comprising a very extensive radio corona, as proposed by Hanbury Brown and Hazard, was not universal, and that in the case of these three galaxies the emission was concentrated close to the nucleus. However, the earlier observations of the similarity in the integrated fluxes was confirmed; it appeared that the total radio emission is closely proportional to the optical emission, irrespective of its concentration to the nucleus.

The Observations

Our new observations are represented by the drift scans shown in Fig. 1. In these, the aerial is pointed at the declination of a galaxy and scanned across it in an east-west direction by the rotation of the Earth. Sidereal time markers are shown at minute and half-minute intervals. Also, under the galaxy records, the east-west extent of the optical image of the main body of the galaxy is shown.

In all cases there exists an extended component of emission roughly co-extensive with the visible galaxy. In addition, both *NGC 253* and *NGC 4945* show the presence of a small bright source close to the centre of the extended component. It is unresolved ($< 0.5'$ arc) in the case of *NGC 253* and of the order of $0.75'$ wide in the case of *NGC 4945*.

Scans were also made at declinations 2° north and south of the galaxy positions. The results were consistent with an origin of the emission entirely within the galaxies, except for the concentration immediately following *NGC 4945*, which may be an unconnected point source at a slightly different declination. For the purposes of analysis it will be assumed to be unrelated to the galaxy, and its contribution to the flux subtracted.

Before discussing our new results in more detail it is necessary to enquire why Mathewson and Rome were

unable to detect the extended components. They quoted angular sizes $\leq 5'$ arc, whereas inspection of the records in Fig. 1 shows that the overall east-west extension varies between about 8' arc for *NGC 5236* to approximately 18' arc for *NGC 253*. Probably their results arose as the combination of several factors. In the case of *NGC 5236* the size is not much larger than their lower limit, so that the failure to observe an extension is probably not significant. Although the extended component is larger in the case of *NGC 4945*, it is quite understandable that the strong central component would dominate the picture. However, the size and integrated emission of the extended component of *NGC 253* would appear to be easily observable. It seems likely that it was not observed because of a rather fundamental difficulty. The resolution of a radio telescope may be controlled by changing the observing frequency, but, if a radio source is completely resolved,

Fig. 1. Transit observations of the three galaxies (a) *NGC 253*, (b) *NGC 4945*, (c) *NGC 5236*. Minute and half-minute time markers are shown and in each case the east-west extent and position of the main body of the galaxy is indicated by the black line immediately below the chart record. The receiver output time constant is 0.8 sec

the received power is proportional to $\lambda^{2+\alpha}$, whereas the received power of an unresolved source is proportional to λ^α , where α lies in the range 0.5–0.7 for the corona of a normal galaxy. Thus, if one increases the resolution by decreasing the wave-length, it becomes increasingly difficult to observe the extended sources which are resolved. This effect is seen in its most acute form in the corona of the Milky Way which, using present techniques, is unobservable at centimetre wave-lengths.

Physical Properties of the Galaxies

Our knowledge of the physical properties of the galaxies comes essentially from the work of de Vaucouleurs. Most information is available about *NGC* 4945, for which values of distance modulus, total absolute magnitude and apparent magnitude are given, together with other photometric data which are not at present relevant⁸. Equivalent data are also presented for *NGC* 253 but not in such detailed form and probably with lower accuracy⁸. Little information is available about *NGC* 5236, and to compare it with the others we have supplemented de Vaucouleurs's data⁷ with *The Hubble Atlas of Galaxies*⁸. To obtain a distance scale, we have assumed that the absolute magnitude is the same as *NGC* 253. This leads to a distance modulus close to that of *NGC* 4945, consistent with the suggestion of de Vaucouleurs that they belong to a single physical grouping of galaxies⁸.

All the galaxies are late type spirals, the earliest being *NGC* 5236, which Sandage denotes as *Sc/SBb*, and the latest being *NGC* 4945, which de Vaucouleurs denotes as *SB(s)cd*. Their basic properties obtained as here are summarized in Table 1: the magnitudes have been corrected for internal, as well as galactic, absorption.

Calibration of the Equipment

The instrument has only recently been put into operation and calibration programmes are at present being undertaken to place the measurements of flux density and position on a suitable absolute standard. For the present observations the right ascensions have been taken directly from the transit times measured on the uncalibrated instrument. Checks which have been made with lunar occultation sources of accurately known position suggest that errors do not exceed 10" arc. The declination is defined with an accuracy better than 0.25°.

The flux density scale is not yet in such a satisfactory state, and for these observations our procedure was to check the calibration at intervals by observations of convenient sources in the catalogue of Bolton, Gardner and Mackey⁹, which gives fluxes of radio sources at 408 Mc/s based on the scale of Conway, Kellerman and Long¹⁰. The accumulated uncertainties appear quite large and our relative fluxes are thought to be accurate only to about ± 15 per cent: the uncertainty in the absolute calibration may also be of this order. This degree of accuracy is considered adequate for the observations recorded here.

Analysis of the Observations

NGC 253. The right ascension of the central source is 00h 45m 05s (epoch 1950.0). The position of the galaxy is given as 00h 45.1m (1950) (ref. 3), so that our observations are consistent with a point source placed at the nucleus of the galaxy. The flux density of the source is 3.5 flux units.

Table 1. PROPERTIES OF THE GALAXIES

Galaxy	Corrected (mpg)	Corrected (Mpg)	Distance (pc $\times 10^3$)	Radius in plane of galaxy (pc $\times 10^3$)
<i>NGC</i> 253	6.5	-20.5	2.5	8
<i>NGC</i> 4945	7.55	-20.35	3.8	8
<i>NGC</i> 5236	7.1	-20.5	3.4	5

After making allowance for the smoothing effect of the aerial beam, the east-west extent of the extended component is approximately 18' arc; this corresponds to an angle of 19.5' arc measured along the major axis at position angle 67°. The integrated flux is 20 flux units.

It is interesting to enquire what spatial distribution of emission would reproduce the observed telescope response. As we have no information about the north-south distribution we have assumed the emission is distributed in a series of uniform spheroidal shells of differing emissivity, centred on the galaxy, and have determined the radial distribution of emissivity along the major axis which best fits our observed galactic profile. A more refined analysis should be possible with the completed instrument.

Using a fan beam aerial which does not resolve the source in a north-south direction, it is easy to show that the radial distribution of emission in a spherically symmetric source is given by:

$$E_\theta \propto \frac{1}{\theta} \frac{dT_\theta}{d\theta}$$

where T_θ is the aerial temperature at the angle θ from the centre of the distribution. With a spheroidal source of unknown ellipticity the same expression may be used to determine approximately the emissivity in the galactic plane at an east-west angle θ from the nucleus. If the ellipticity is large or the major axis nearly east-west, the errors will be small and probably negligible compared with uncertainties introduced by random noise and unresolved sources. It is worth pointing out that the foregoing equation implies that a line scan of an infinitesimally thin spherical shell produces a rectangular response.

The observed profile can be fitted quite well by a three-component model as follows: (1) an unresolved nuclear source with a radius less than 200 pc. and a total emission of 2.6×10^{21} W(c/s)⁻¹; (2) a less-concentrated component of uniform emissivity, radius 2.5 kpc and total emission 5.5×10^{21} W(c/s)⁻¹; (3) an extended component of uniform emissivity, radius 7 kpc and total emission 9×10^{21} W(c/s)⁻¹.

Using the same distance scale, the overall radius of the visible galaxy is approximately 8 kpc. A bright central structure can be observed extending out to about 3 kpc, perhaps corresponding to our second radio component. The nucleus is not evident on photographs available to us.

NGC 4945. The right ascension of the central source is 13h 02m 33s (epoch 1950.0), and its flux density is 9 flux units. The position of the galaxy is given as 13h 02.4m (ref. 7). The galaxy is observed edge on and the relatively heavy obscuration hides the nucleus so that the optical position must be judged from the rather irregular brightness distribution. The agreement is sufficiently good to be sure that we are observing the galaxy.

We have analysed the extended component in the same way as before, but this time find that a single ellipsoid of uniform emissivity is adequate to fit the observation. The total flux density is roughly 10 flux units, with some additional uncertainty because of the small source close to the galaxy.

Thus, after allowing for a position angle of 42°, the observations may be represented by the following two-component model: (1) a central, presumably nuclear, source with a radius of the order of 400 pc and total emission 15×10^{21} W(c/s)⁻¹; (2) an extended component of uniform emissivity with a radius of 8 kpc and a total emission of 17×10^{21} W(c/s)⁻¹.

The radius of the visible galaxy is also about 8 kpc so that the second component here corresponds to the third component in *NGC* 253, both having the same extent as the visible galaxy. An intermediate component may be present in *NGC* 4945, but it is not separately distinguishable.

NGC 5236. This galaxy is in a rather confused region of several radio sources. Nevertheless, a small extended

source at the galaxy position is quite clear. There is no obvious nuclear component so that it is difficult to quote an accurate position. The centroid of the whole source is approximately 13h 34m 11s, which agrees well with the galaxy position of 13h 34.3m (ref. 7). The integrated flux density of the whole galaxy is 5 flux units and its overall extent, after allowing for the aerial resolution, approximately 8' arc. In this example the galaxy is seen face on so that there is no need to allow for the position angle of the major axis.

Because of the poor signal-to-noise ratio and the presence of confusing sources, an attempt to separate different components is not justified. Although there does appear to be evidence of fine structure, a simple model comprising an ellipsoid of uniform emissivity fits the observations reasonably well. The total emission is 6×10^{21} W(c/s)⁻¹ and the radius of the distribution approximately 4 kpc. As this is close to the radius of the visible galaxy, the component appears to correspond with the extended components in the other galaxies.

Discussion

We have found that all three galaxies examined have extended components of radio emission co-extensive with the visible galaxy and of the same order of total emission. The ratio of optical emission from the whole galaxy to the radio emission of this component is also roughly the same in all cases. Additional more concentrated components exist in two of the galaxies, but not in any fixed ratio.

Apparently similar components have also been recognized in the Milky Way, where we have a nuclear source, a disk component with the greater part of the emission confined within a radius of about 6 kpc and, finally, a corona of approximately uniform emissivity extending to about 12 kpc in the galactic plane¹¹. The average overall extent of the Milky Way itself, including the Perseus arm, must be about 13 kpc.

It appears to be very reasonable to identify the Milky Way corona with the extended components found in the other galaxies: the disk and nuclear components at the distance of these galaxies would be too weak to be detectable. Both NGC 4945 and NGC 253 have, by contrast, very strong nuclear components. In order to avoid postulating an additional galactic component, it also seems reasonable to identify, tentatively, the intermediate extended component of NGC 253 with the disk component of the Milky Way. Although this component is relatively much stronger in NGC 253, it appears to be related to the visible structure of the galaxy as in the Milky Way.

In Table 2, we accept these suggested identifications and compare the galaxies directly. Values for the disk and corona of the Milky Way have been taken from the 85 Mc/s results¹¹, assuming an emission proportional to $v^{-0.6}$ and a distance to the nucleus of 10 kpc. The emission

Table 2. RADIO PROPERTIES AT 408 Mc/s

	NGC 253	NGC 4945	NGC 5236	Milky Way
Nucleus: emission W(c/s) ⁻¹ $\times 10^{21}$	2.6	15	Undetected	0.04
Radius pc	<200	~400	—	200
Disk: emission W(c/s) ⁻¹ $\times 10^{21}$	6.5	Undetected	Undetected	0.5
Radius pc $\times 10^3$	2.5	—	—	6–10
Corona: emission W(c/s) ⁻¹ $\times 10^{21}$	9	17	6	7
Radius pc $\times 10^3$	7	8	4	12
Visible galaxy				
Radius pc $\times 10^3$	8	8	5	13
Radio index M_{408} -Mpg				
(a) Corona	+2.4	+1.5	+2.7	+2.6*
(b) Whole galaxy	+1.7	+0.8	+2.7	+2.5*

* Assuming the Milky Way has the same absolute magnitude as NGC 253, that is, $M_{pg} = -20.5$.

of the nucleus itself has been obtained directly at 408 Mc/s using the present instrument.

Although these results make a satisfactorily coherent picture, it appears that the only other spiral galaxy to be studied in detail, the Andromeda Nebula, has much more extensive radio components, although the total emission is similar. Observations at 408 Mc/s using the Jodrell Bank 250-ft. reflector¹² may be compared directly with ours if we assume a distance of 8×10^6 pc to the galaxy⁸. After allowing for the beam-width, the results appear to indicate a coronal component of total emission 10×10^{21} W(c/s)⁻¹ extending to a radius of about 40 kpc along the major axis, and a disk component of emission 0.6×10^{21} W(c/s)⁻¹: the extent of this component is uncertain as it was not completely resolved, but it is probably of the order of 12 kpc along the major axis. No nuclear component was detected. The main body of the galaxy, however, has a radius of only about 14 kpc.

Thus, if this interpretation of the observations is correct, it appears that the distribution of coronal radio emission in the Andromeda Nebula is not similar to the distribution in the other spiral galaxies. Clearly, it will be necessary to observe many more galaxies with high resolution to establish the pattern more reliably.

WILSON'S THEORY OF ICE AGES

By JOHN T. HOLLIN

Department of Geology, Princeton University, New Jersey

A PAPER by A. T. Wilson¹ suggests that the Antarctic ice sheet is unstable: that it builds up until it begins to melt at the base, then 'surges' rapidly outwards to form a large floating ice shelf in the Southern Ocean. Wilson suggests that, in the Tertiary, shelves formed in this way periodically displaced enough sea-water to account for the cyclothems of that time; and that in the Quaternary, helped by some longer-term reduction of temperature, they periodically cooled the oceans enough to cause ice ages in the northern hemisphere. A paper

by me² points out that, if these shelves did cause ice ages, traces should exist of (otherwise anomalous) rapid but temporary rises of sea-level, of 30–100 ft., just before each ice age. This present article discusses the available evidence for and against such rises. Up to now, most of the evidence seems favourable to Wilson's theory.

'Surges' and 'catastrophic advances' in glaciers have received increasing attention recently. More than forty such events have been reported from Alaska and north-west Canada alone³. The largest surge reported so far is

Fig. 1. Bråsvellbreen, looking northwards. Only the western and eastern edges (30 km apart) are shown. A (and to the right), 'normal' ice cap; B, Bråsvellbreen; C, moraines and rocks; D, Barents Sea. (Photographs by Norsk Polarinstittutt, 1938)

probably that of the Bråsvellbreen (a sector of a roughly circular ice cap in Spitsbergen), which advanced up to 21 km on a front of 30 km, some time between 1935 and 1938 (ref. 4) (Fig. 1). The fastest surge measured so far is probably that of the Kutiah Glacier¹, at 110 m/day, although hearsay surges include one so fast that it overtook two villagers fleeing from it⁵. The cause of surges is unknown. In Robin's theory, which Wilson quotes, surges occur when the continuing build-up of the glacier allows geothermal and frictional heat to bring the base to the melting-point. Once melting begins, large glaciers may find it difficult to expel the large amounts of water they generate and, in Weertman's theory⁶, it is the resulting basal water layer which accounts for the high speed of the surges. Now, without further work on these and other theories, it is really impossible to say whether or not surges should occur in large ice caps and ice sheets, and I have personally been somewhat sceptical about such surges^{7,8}. However, so as to test Wilson's theory, in order to know what to look for in the geological record of sea-level changes, it is worth while trying to estimate how large and how fast his surges would have to be. My estimate that they would have to involve sea-level rises of 30–100 ft. was based mainly on the assumption that surges smaller than this would have too short a period to fit the time-scale of ice ages, and on the fact that deglaciations larger than this are almost impossible to imagine glaciologically, at least without moving Antarctica northwards. To illustrate this, we can refer to some of the known facts from Antarctica⁷. The current average thickness of the ice sheet there is roughly 2,300 m. Suppose that this builds up to 2,400 m. Suppose that a surge emerges from either Wilkes Land or the Filchner area, captures the drainage⁹ from half the ice sheet, and lowers that half by 50 per cent. Such a surge, spread out to the typical ice shelf thickness of 200 m, would reach 55° S and, as Wilson points out, would appreciably increase the Earth's albedo. The central thickness of the ice sheet is roughly 4,000 m. The central accumulation rate is roughly 3 g/cm² yr, so that a central lowering by 50 per cent would take approximately 70,000 yr to build up again. Very roughly, this would be the period of the surge. The surge just described would be in the middle of my estimated range: ignoring isostatic effects, it would raise sea-level by 65 ft. On the speed of the surges, if they are in fact a cause of ice ages, then they must certainly be rapid to overwhelm the great capacity of the Southern Ocean for breaking up and melting Antarctic ice¹⁰. It is interesting, therefore, to realize that if the ice in the centre of the ice sheet began to surge with the velocity of 110 m/day quoted above, it would in fact reach the edge of the ice sheet in only 40 yr.

These estimates of the size and speed of Wilson's surges are incorporated in Fig. 2. Fig. 2 (1) shows the conventional view of sea-level change during ice ages such as the Weichsel (Würm, Wisconsin), with the Antarctic ice sheet remaining roughly constant in volume. Fig. 2 (2) shows the sea-level change required by Wilson's theory in Tertiary time: rapid rises accompanying the surges from Antarctica, and slow falls accompanying the build-ups there. Fig. 2 (3) shows the change required for Quaternary time: a rise accompanying each surge, a fall as both the Antarctic and northern ice sheets build up, the end of the ice age and a levelling out as the northern ice sheets disappear, and a subsequent small fall accompanying the final build-up in Antarctica. Although these estimates are very speculative glaciologically, they form a very specific test geologically. The chances seem small that rapid rises of sea-level of 30–100 ft., repeated in several interglacials at precisely the break of climate, could be caused by anything other than Antarctic surges.

As might be expected, the most detailed evidence for and against the sea-level changes of Fig. 2 (3) comes from the uppermost, most-studied part of the Quaternary, especially from north-west Europe. In this area, sea-level movements are recorded by changes in the land- or sea-shell content of deposits, and the date of the movements is recorded by the pollen content. Each of the last few interglacials in north-west Europe can be divided now into several pollen zones, and this permits very accurate dating. Within north-west Europe, the best areas for an investigation of this type appear to be southern England and northern France, where the horizontality of old, high-level marine features suggests that these areas are essentially stable. Not so many deposits have been examined there as in Holland and Germany, but in those areas there has been considerable warping, and it is difficult to reconstruct the old elevations involved. Fig. 3, therefore, is an attempted reconstruction of sea-levels during the last two interglacials in southern England. (For the Hoxnian interglacial, it has been necessary to

Fig. 2. Three patterns of sea-level change. The time and elevation scales are compressed in the ice ages. A, absent; G, growing; H, shrinking; R, roughly constant in volume; S, surging

use some data from eastern England, and in this particular case the possibility of warping is discussed below.) Sea-level positions suggested by field studies are plotted, and an attempt is made to connect them with a curve of the Fig. 2 (3) type. How well this curve fits the data is discussed in the following four paragraphs. For those interested, the pollen zones and the sites of Fig. 3 are discussed more fully in papers by West¹¹ (note that, in ref. 11, the legends of the key Figs. 12 and 13 should be interchanged).

In Fig. 2 (3), the sea-level just before a surge changes only slowly, whereas after a surge it changes rather quickly, because not only the Antarctic but also the northern ice sheets are now building up. Therefore, marine benches are more likely to be cut at a primary, pre-surge level than at a secondary, post-surge one. Accordingly, to agree with those authors who argue that a marine bench between 5 and 30 ft. O.D. in south-west England and north-west France must belong to the Hoxnian interglacial^{11,12}, I have attributed elevations in the middle of this range to the primary Hoxnian level in Fig. 3. What is striking is that the pollen data from the Hoxnian show that late in the interglacial, at the end of the main warm zone 2, apparently just as the climate broke, a remarkable transgression occurred in eastern England. The transgression has been recorded at 9 ft. at Clacton¹³, at 21 ft. in the Nar Valley (where marine deposits continue to at least 65 ft.)¹⁴, and at 80 ft. at Kirmington¹⁵. The record of freshwater sedimentation at Southelmham¹⁶, at roughly 80 ft., ends at the end of zone 2, and would fit a transgression at that elevation at that time. It seems reasonable to assume that the upper limit of the transgression was the 100-ft. 'Tyrrhenian' beach and 'Boyn Hill' terrace level traditionally assigned to the Hoxnian in southern England and elsewhere. The fact that the transgression occurred at all these different elevations at the same time suggests that it was unusually rapid. This rapidity makes it very unlikely that it was due to downwarping. For example, let us, to avoid the effects of tilting, focus our attention on the one small area of the Nar Valley¹⁴. The 21-ft. difference in elevation between the uppermost zone 3 marine sediments at Summer End and the uppermost freshwater sediments at Horse Fen suggests that at least that amount of transgression must almost certainly have occurred in that relatively short zone. It is difficult to suggest what could have caused a downwarping at this rate, which has obviously not been maintained since. That the transgression at Clacton was the result of a eustatic rise of sea-level rather than of downwarping has already been argued, by Oakley and Leakey¹⁷. They claim that, for the Clacton area, the rise to the Boyn Hill level is represented by the gravels at 85 ft. at Upper Dovercourt.

In the last, Ipswichian (Eemian, Riss-Würm, Sangamon) interglacial, early in the main warm zone *f*, the sea is known to have risen above -5 ft., at Selsey¹⁸. Presumably this was the end of the post-Riss rise, because appreciably later in zone *f* the sea was still at -2 ft., at Stone¹⁸. By the end of zone *f*, river flood deposits were being laid down at -3 ft. at Trafalgar Square¹⁹, which suggests that the sea had by now fallen a little below that level. Now, exactly when the Ipswichian climate began to deteriorate is difficult to say, but it was almost

certainly in zone *g*²⁰. What is striking is that in that zone a transgression occurred in north-west Europe. The transgression is very well documented in north-west Germany^{21,22} and, elsewhere, it seems to have formed the Eemian 'Portlandia Sea' of the Baltic²³ and the 'marine intercalation' of Holland²⁴. The German pollen data in particular favour a transgression in the first half of zone *g*. At about this time in England, a remarkable aggradation occurred in the Thames estuary where, at 23 ft. at Ilford²⁵, pollen-bearing sediments were covered by the well-known Thames 'brickearth' or silt. Because of the low percentage of *Carpinus* in the uppermost sediments at Ilford, West *et al.* attribute them to the end of zone *f*. However, because low percentages of *Carpinus* can sometimes occur in zone *g*²⁰, and because, otherwise, the percentages of *Pinus*, *Quercus* and *Corylus* in the uppermost sediments are quite typical of that zone, it seems quite likely that all these north-west European pollen dates reflect the same event. At Ilford, the aggradation of the brickearth continued to 42 ft., and at other places in the estuary to 50 ft. Since the gradient of the Thames and its terraces in this area is less than 3 in./mile (ref. 26), it seems quite possible that the aggradation of the brickearth was in fact a response to a rise of the sea to the 50- or 60-ft. 'Taplow', 'Main Monastirian' level traditionally assigned to this interglacial. That the Main Monastirian level may indeed have been merely a secondary one (from which the sea immediately began to drop to its Würm level) is suggested by the fact that it is only rarely a bench level, but is chiefly a beach and river terrace level²⁷. Similarly, in North America, although the coastal Cape May formation, assigned now to the last interglacial²⁸, was attributed by Salisbury and Knapp to a sea reaching 50 ft. or so, they remarked that only faint terraces rather than coastal cliffs were to be found at that level²⁹. Of course, as well as the 55-ft. Main Monastirian, a 25-ft. 'Late Monastirian' level²⁶ is often assigned to the last interglacial. This 'double' level is a problem for any theory of ice ages, but, according to Fig. 3, the Late Monastirian level might represent the brief reoccupation of the primary Hoxnian level by the regressing Hoxnian and Ipswichian seas. The Ipswichian regression across O.D. in zone *i* was recorded in northern France¹⁸.

The Ipswichian interglacial provides the only evidence I have been able to find that is plainly incompatible with the reconstruction in Fig. 3. In eastern England, the Histon Road, Cambridge, deposit³⁰ lies at 15-42 ft. O.D., but shows terrestrial as opposed to marine sedimentation between zones *g* and *i*. Now, because this is the only deposit of its kind so far, it is possible that it is deceptive in some way. One possibility is that the unconformity 500 cm below the top of the deposit, that is, at 25 ft. O.D., does represent a marine interval. The sediments below 500 cm contain high percentages of *Quercus* and *Corylus*, and could quite easily belong to the first part of zone *g*. Then, as Sparks and West point out, a true zone *h* is missing in the deposit, and it is possible that sedimentation above 500 cm did not begin again until zone *i*. If so, the unconformity would fit Fig. 3 exactly. Other East Anglian evidence, such as the 55-ft. Ipswichian terrace at Cambridge³¹, certainly fits Fig. 3. However, although the data from Histon Road are insufficient by themselves to disprove the reconstruction of Fig. 3, they do emphasize one of its chief weaknesses: the shortage of really high quality evidence for an Ipswichian sea-level above O.D. As we have seen, the north European data, the Thames evidence and the Monastirian tradition do favour such a level. However, evidence that would really favour Wilson's theory would be aggradation deposits similar to the Ilford ones in other estuaries, or, better, zone *h* marine deposits in the 20-40 ft. range. Because a late Ipswichian sea-level rise would have been short-lived, and the marine extension shallow, and because any deposits in it would afterwards have been

Fig. 3. Sea-level changes suggested for England. The time and elevation scales are compressed in the ice ages. The dots refer to pollen studies: C, Clacton; N, Nar Valley; K, Kirmington; S, Southelmham; T, Trafalgar Square; I, Ilford.

leached, frost-heaved and eroded for the whole of the Weichsel, such deposits, if they exist, may be hard to find. On the other hand, if they cannot be found, and if more deposits such as the Histon Road one are discovered, then these latter would be strong evidence against Wilson's theory, at least as it applies to the latest ice age.

In the current interglacial, since the northern ice sheets disappeared, Wilson's theory requires that sea-level should be falling slightly, as the Antarctic build-up continues. It is possible, of course, that a fall is being offset by continuing glacial retreat in the Canadian archipelago or Greenland, or even by minor surges from Greenland or Antarctica. However, there are many papers which do document a falling sea-level over the past few thousand years^{32,33}. On the other hand, a probably larger set of papers describes a rising sea-level³⁴. At present, the difference between these results cannot be explained, although it may be due, for example, to local land movements³⁵. In this situation, an indication of the world-wide average movement of sea-level might be given by the change, if any, in the Earth's rate of rotation. Analysing the change suggested by the data from ancient eclipses, Munk and MacDonald³⁶ conclude that there may have been a fall of sea-level of 2 m over the past 2,000 years, and this of course would favour Wilson's theory. A fall of 2 m in 2,000 years would be equivalent to a continuing 25 per cent surplus of accumulation over ablation in Antarctica (assuming that the area of the ice sheet is 1/30 that of the oceans, and the average accumulation on it 14 g/cm² yr)⁷. This is larger than the 5 per cent surplus which, ideally, is all that would be required to replace the late Ipswichian surge of Fig. 3 over the roughly 100,000 yr since it occurred. However, the figure of 5 per cent would be bigger if there have been minor surges since the late Ipswichian one. (Such surges could have been one cause of Weichsel 'stadial' advances.) Glaciologically, even a surplus of 25 per cent cannot really be distinguished yet in Antarctica, because our knowledge of ablation rates there is so very limited⁸. The known activity of the ice sheet at the edges of Antarctica suggests that if any build-up is occurring it must be concentrated in the centre of the continent. Evidence for or against this may come in a few years from Franco-Soviet and other strain measurements in that area: evidence that the ice is stretching at less than the rate required to dispose of the snow accumulation would support Wilson's theory.

So far, I have said little about the speed of the sea-level rises. Obviously, our first problem is to find out whether they really occur or not. There are two reasons, however, for saying a little more about their speed. First, Wilson's theory implies that the current interglacial will end with a new surge, perhaps suddenly, some time between now and say A.D. 50,000. Since, from Fig. 3, the sea might rise then by 75 ft. or so, the speed of the rise might have important human implications. Second, chiefly for the purpose of drawing Fig. 2, I mentioned a possible surge time of 40 yr. However, a sea-level rise much faster than this might have left some very unconventional deposits, and unless this is appreciated, these deposits may remain unrecognized. To illustrate this point, let us look, for example, at the brickearth, laid down during the late Ipswichian aggradation in the Thames estuary. The brickearth consists chiefly of silts, which are locally 30 ft. thick but which, unlike the alluvium of the current interglacial, are quite devoid of layers of vegetation, developed during intervals of sub-aerial exposure. These silts are famous for their numerous, curiously intact remains of large mammals. Many geologists have argued that the silts must have accumulated, and the mammals drowned, during floods much greater than those known to-day³⁸. The brickearth is extremely patchy and, indeed, the alluviation of the whole Thames estuary, from below -3 ft. to above 50 ft.,

would represent an enormous amount of deposition for the end of an interglacial, when if anything the Thames should have been incising rather than aggrading. Also, despite their situation, the shells in the brickearth are overwhelmingly freshwater ones, and only rarely estuarine ones. So long as Wilson's theory is being discussed, the possibility ought to be borne in mind that in fact the brickearth never was a normal alluvium, but was merely the soil and fauna of zone *g*, re-worked by a very rapid rise of sea-level, and swept into the embayments of the marine extension. Only after this diluvium had settled would conventional estuarine and marine deposits have begun to accumulate above it and, as we saw two paragraphs ago, such deposits may be hard to find. (The same possibility ought to be borne in mind for the brickearth at Stutton^{11,37}, where the evidence is otherwise incompatible, though not decisively so, with the curve of Fig. 3. Note that the data from nearby Bobbitshole³⁸ fit Fig. 3.)

Even if these late interglacial transgressions do prove to have been very rapid, determining their precise velocity may be difficult, except in one eventuality. As opposed to the Kutiah velocity in the second paragraph, the hearsay velocity (presumably several km/h) yields a surge time of only 1 week. Now a surge in only 1 week or so would involve a very rapid redistribution of ocean water, and the question arises whether or not the sea-level rises might have occurred in the form of waves or 'tsunamis', such as sometimes run several miles inland when they break on the coasts of the present-day Pacific Ocean³⁹. This is a possibility that can be tested, as follows. Let us look this time at the Hoxnian interglacial, for which a secondary, post-surge coastline of 100 ft. was suggested. If waves occurred, sediment-pollen studies some way inland from that contour should detect some disturbance at the time of the surge. The waves would be unlikely to have left any marine traces, such as shells, but they might have left a layer of debris, such as gravel or tree trunks. So far, I have been able to find only one investigation from such a situation, from Kilbeg⁴⁰ in southern Ireland. The profile there does show an unconformity covering the break of the Hoxnian climate, but the gap covers too long a time to be good evidence for waves. However, if further investigations in such situations can be found or made, it should be possible to complete this test.

If all large glaciers are indeed susceptible to surges, either because of the instability discussed above or, though this seems less likely, because of some external cause, then this raises many interesting questions. One of the most interesting must be whether or not surges of the Gondwanaland ice sheet may account for the Carboniferous cyclothems, especially for the rapid submergence of the coal beds. However, although these questions do deserve our attention, it looks as though the most rigorous progress in the matter of surges will be made by concentrating on Wilson's theory of Quaternary ice ages, particularly on events late in the last interglacial. As was mentioned earlier, the sea-level test for Wilson's theory is a very specific one, and it is certainly intriguing to find these traces of late interglacial transgressions with exactly the required timing, amplitude and speed. One explanation which might be advanced for them would be that they were merely continuations of the main post-glacial transgressions, and due either to a normal (as opposed to surge) deglaciation of Antarctica by the continuing warmth of the interglacial⁷, or else due to local downwarping. Another explanation would be that they were merely recoveries from a regression due to a cold spell in the middle of the interglacial. Up to now, Fig. 3 and the foregoing discussion are strongly against these explanations, and are favourable to the Wilsonian explanation. There is clearly a need for more data, but there seems little doubt that further work along these lines will complete the test of Wilson's theory.

I thank G. Denton, D. Fullerton, B. C. McDonald, Dr. J. F. Nye, Dr. R. G. West, Prof. S. Judson and Prof. H. H. Hess for their advice.

"THERE IS ALL AFRICA"

By DR. A. S. THOMAS

EVER since the first explorers penetrated the centre of Africa, Europeans have desired to bring peace and prosperity to the continent; the most striking proof of that desire has been the devotion and self-sacrifice of the missionaries. But there was often a bland assumption that European methods of clothing, farming and political organization could be applied without modification near the equator. In courses of training for work in the tropics there was much emphasis on primitive agriculture—unchanging and resistant to change.

But, as a farmer's son who had done much hard work, some of which seemed unnecessary, I found myself thinking how sensible the Ghana farmers were to grow their cocoa crops with a minimum of work. Their mixtures of food crops looked untidy after European monoculture, but many of these crops had been introduced to Africa, some in the far past, some recently—bananas and cocoyams from Asia, cassava, other cocoyams, maize and sweet potatoes from America—and their culture must have involved great changes.

The Krobo farmers explained that their farms were in strips across the valleys because that was the only fair way of dividing the land—there was one kind of soil on top of the hills, one on the sides and one in the valleys. That important point had not been mentioned in any of the lectures on soil science to which I had listened, though the same sense of values had led to division of much of southern England into long strips of parishes. My appointment in Ghana lasted only for one tour; money was short in 1930 and there was considered to be no need for research on cocoa; six years later a Ghana farmer took specimens of swollen shoot to the Division of Agriculture and asked why his cocoa was dying.

On arrival in East Africa, I found that the soil chemists were studying soils in series or catenas. Most of Africa is a vast peneplain of old land surfaces dissected by water-courses; there are few level areas except the plains of dark clay which are under water for part of the year, dry and deeply cracked for another part; even these plains show slight differences in levels; parts which are submerged for much of the year must be considered in conjunction with the higher ground on which wild and domestic animals graze during the rains.

People are taught about Africa from small-scale maps which cannot show the undulating surface or the variety of vegetation associated with it; then some people go to Africa expecting to see vast stretches of virgin forest, their false ideas having been reinforced by travel films—"And so we set off through the African jungle", taken in a place where there is no jungle, only the coffee bushes shown on the screen. Even when African forests are tall, they may be quite young; a patch in the Botanic Gardens, Entebbe, Uganda, is so fine that it has been used as the setting for a "Tarzan" film; but a photograph shows that fifty years ago it was a grove of raphia palms without any trees.

Many theories have been postulated about tropical forests on the assumption that the areas examined were climax communities when, in reality, they were unstable young phases of forest growth. Even the woodland areas have been represented as climax, with maximum energy flow; the exposed strata on any river bank of such an area will show that there has been no stability; the layers of water-borne and wind-borne deposits prove there has been no stable state, only a sequence of changes.

Philosophical phrases such as "Man in harmony with his environment" would not mean much to an African peasant whose blood is invaded with malaria parasites, whose farm is invaded by elephants, monkeys and wild pigs. When you have recurrent dysentery and malaria you come to regard your body, not as an individual, but as an ecosystem; one man, who had a tapeworm as well, used to say: "We have enjoyed our meal".

Conservationists talk and write of man as a destroyer, not mentioning the way in which man builds up the soil of his settlements. There are many proofs of this building-up: the depth of deposits in old European cities, the huge mounds which cover ancient cultures in the desert areas of Africa and Asia, and the deep layers of broken pottery on some hill tops in the wetter parts of Africa.

Furthermore, the soils of settlements are richer than those of the country around them. Saltpetre used to be extracted in India from the soils of places where there were dense populations of men and domestic stock, and a residue of ashes from wood fires—conditions which can be matched in Africa. Africans select former village and

cattle kraal sites for the cultivation of crops like bananas and tobacco which demand high fertility. The banana is a most useful indicator plant in the wetter parts of Africa, for it will flourish and persist only on rich soils like those of the western slopes of Mount Elgon which have an agricultural population of several hundreds, even more than a thousand, per square mile.

If a house of wood and grass is deserted, it soon rots away under an equatorial climate; no trace will remain above ground, and the only clue will be in the soil—the local accumulation of bases, especially of lime, which is easily detected by tests for soil acidity. Some crops may benefit from the presence of bases; others, such as the tea plant, will die out in patterns to show the plans of former villages, proved by abundance of potsherds.

Certain trees often indicate former settlements; in the drier parts of Africa, the baobab, *Adansonia digitata*, is largely confined to past and present settlements; in the woodland areas, groups of very large shea butter trees, *Butyrospermum parkii*, are to be seen in the villages, or where the villages have been.

Chlorophora excelsa, a magnificent tree of the forest zone, is associated with the spirits of ancestors both in East and West Africa; the belief seems founded on the fact that the tree needs rich soil and protection from fire, conditions usually only found on farms. Soil tests near many *Chlorophora* trees on farms, in forests and woodlands, always showed the soil to be more alkaline near the tree than at a distance from it, where the soil often was too poor for the tree to grow. Yet this tree has been used to denote plant associations without mention of its restricted growth or of the unsuitability of the soil for its growth. It is restricted to settlements, just as in many grasslands the shrubs are restricted to the termite mounds, the soil of which is less acid than the rest of the land.

Diversity of soil is a usual feature in Africa; soils on the hills are always different from soils in the valleys, and the incidence of human settlements and termite mounds is likely to give diversity to the soils in any single zone; hills not very far apart may show distinct differences in their soils and in the way in which they are used¹. "In Ghana, soil series rarely cover a sufficient area in individual expanses to make it practical to map them on any but very large-scale maps"². Yet there are still being produced maps which show generalized arbitrary classifications; it is most interesting to consider places which one knows well, to compare the different classifications by people who may or may not have visited the area and to think how untrue these classifications represent the actual vegetation.

There are many difficulties in African ecology. More than twenty years ago I discussed the difficulty of learning the names of the plants with another man and found that he, like me, after two years in Africa had felt that he would never be able to learn the names; but that, again like me, after three years suddenly found that he knew enough names to make ecological investigations without taking a large number of specimens for determination in the herbarium. We were both quite intelligent, both very hard-working; and I refuse to believe that much good work could be done by those who write descriptions after a few weeks in Africa, looking at plants they had not seen before.

Furthermore, as Buxton showed, the aspect of any small piece of African vegetation alters completely with the seasons³; the eye selects those species which are in flower at the season when they are viewed. So I made it a rule never to publish an account of any patch of vegetation unless I had visited it at different seasons and had described it without reference to previous notes. Yet many of the papers describe large areas after very short visits; if work is done carefully and factually, it must be confined to a small plot; and there is no justification for extending such a description over a region. Yet

once a description is in print, it is regarded as factual and is reproduced in the text-books.

The ease and rapidity of modern travel only add to the unreliability of some accounts founded on observations from a motor-car. A road may seem to pass through dense forest when in reality there is only a screen of trees hiding the farms and villages; but in open country a road may pass through a string of farms although the land away from the road is not cultivated. An expert whom I was escorting through Uganda once stopped the car and said: "You have told me that *Cynodon dactylon* is not important in the natural grassland of this region; we have been through a belt of it, fifty miles wide". I tactlessly suggested that the belt was fifty miles long and ten feet wide, as he could see if he got out of the car; he did not, and he did not speak to me for the rest of the day as he was so angry that neither I nor the grasses conformed to his ideas.

In the old days, when aeroplanes flew low and slow, ecology could be done from them, but that is seldom possible from modern jet airliners. But air photographs are a most valuable means of survey; they show intricate patterns of fields, fallows, grasslands, woodlands and forests which give a truthful picture of the countryside, quite different from the generalized subjective accounts so often printed. The camera is objective.

One thing which horrifies visitors to Africa is the intensity of the fires which sweep through woodlands and grasslands. But Africa has been burnt over for many hundred thousand years; some fires are started by lightning and, long before there was any farming, fires were used in hunting and collecting honey. On my first visit to Mount Kadam, my Karamojong porters were astonished at my anger when they burnt a patch of forest to get a pound or so of honey, and they thought me fussy when I made them extinguish every spark. They looked on fire as part of the climate, and so do many African plants; a large living collection of Uganda grasses dwindled under cultivation, in spite of careful weeding; but when, in desperation, I set fire to them, they responded with normal vigorous growth.

There has been much outcry about the destruction of organic matter, but agricultural scientists are now agreed that burning is the only feasible way for the African farmer to get rid of rubbish before planting his crops. The burning of grassland has been condemned, but many people are coming to realize that it is the only practicable way to clear the mass of dry inedible stems and to produce flushes of young leaves for livestock during the long dry seasons. The wild animals, especially the smaller antelopes, also benefit from this burning; they dare not venture into tall unburnt grass, for fear of predators, and often may be seen grazing close to the cattle; the films usually show them on short young grass but do not show the cattle. Furthermore, in controlled experiments it has been found that the soils of grasslands burnt every year may contain more organic matter than do the soils of unburnt forests on similar ground.

Where there are cattle in Africa, there is usually erosion. It is not the treading of cattle which has attracted attention, but the grazing; yet in reality the treading is the main cause of erosion, for it makes the surface soil hard and as impermeable as concrete, so that the water rushes off and the lower layers remain dry as in a desert. Goats have caused much erosion in Mediterranean countries, but not in tropical Africa; when cattle are driven away from a place through the spread of tsetse fly, and only sheep and goats can be kept, the grass cover will improve; sheep and goats graze more closely than cattle, but they tread more lightly.

Agriculture in temperate regions is changing rapidly, and so is the attitude to change; it is welcomed. The outlook towards African agriculture is changing; there used to be elaborate statistical experiments to give proof of small differences of yields per acre, under conditions

where it was labour and not land which was the limiting factor; many panaceas have been recommended during the past thirty years—green manure crops, contour ploughing and mixed farming are some of them. But an increasing number of agricultural scientists are now demonstrating the wisdom of African farmers, of mixed planting to cover the soil and of giving a minimum of cultivation. We used to be taught that cultivation was necessary; my belief in it was shattered by an old Muganda's explanation of the vigour of a magnificent spreading coffee tree outside his house: "I sweep the ground every day".

Ecology is changing; as Raup showed in his address to the Jubilee Meeting of the British Ecological Society, Clementian ideas of plant succession have been much modified or discarded in America⁴. The influence of these ideas, alas, has extended to Africa. "Ecological studies in the tropics and sub-tropics have been dogged by attempts to fit the observed facts into a framework of classification tracing back to the ideas evolved in temperate Europe and North America, usually those of the schools of Cowles-Clements-Tansley or the Zurich-Montpellier group. The results are often worse than useless; they are misleading, and he who wants a knowledge of the ecological units present in a region has to disentangle factual descriptions from abstract discussion of successional relationships."⁵

The travellers who went to Africa in the nineteenth century had no abstract ecological concepts; they described what they saw, and their writings seem factual, all except those of Stanley, who was a journalist and wrote for effect; if he had known those concepts, he would have used them even more than do some journalists at the present day. Truth of the other accounts has been checked by careful examination on the ground and has shown some astonishing changes; for example, there is no doubt that one hundred years ago there were in Uganda far more people and far fewer trees than at present.

There have been many modern maps of Africa which were compiled by people much influenced by theories and philosophies, based on concepts which cannot be grasped by those who doubt their validity. Even the word 'ecosystem' can have no precise meaning in Africa, where mammals migrate for hundreds of miles and birds for thousands of miles; no region is free from influence outside it; there has been much outcry about the advance of the Sahara, but little mention of the great benefit from the vast quantities of base-rich desert dust brought down by the harmattan wind.

Changes are rapid in Africa. I recently took back to Africa some of the photographs which I had made about thirty years before; they proved changes which I had not expected. Cameras have no ecological concepts, they record facts; and the facts, not the concepts, will be useful in the future.

There is a great danger that, with increasing education, much of the traditional lore of African peoples will be lost, that Africans will place too much trust in the written word. It took me years to work out that the only feasible explanation for localized patches of reddened soil was that they were sites of settlements; an African assistant said: "You are quite right, sir; our people have always known that", and gave instances which I had not noticed. There continue to be many theories about the origin of lateritic ironstone from natural causes, but little attention to the frequency of worked stones, even of grindstones, in it.

Tribal history may be more significant than any survey in the explanation of existing vegetation. There were many wars between Ashanti and the Ivory Coast, so the forest on the borders is young, growing over former farmland. The Mabira Forest by the River Nile, on the borders of Buganda and Busoga, is tall, but it also is young; soil tests for a tea planter indicated a house site

in an unlikely spot; a fortnight later, the headman who was clearing the land greeted me: "You said truly, sir; when we dug where you said the house had been, we found this, and I kept it to show you". It was a hand-made hoe, the most treasured possession of a farmer and buried in the floor of his house; he had been killed or enslaved, the house had disappeared; only the hoe was left, sealed in the clay; and it was not even rusted.

Much of Africa has been photographed from the air to give a true picture of the general aspect. If this photography is combined with objective recording along transects and not by subjective surveys, then a factual and more detailed description is obtained. Specimens can be correctly identified by reference to herbaria like Kew, where floras of the African regions are being compiled. There is need for some agreed system of recording, so that the results for one country can be compared with those of another; and there is need for simple descriptive words like woodland, instead of imported vernacular terms like savanna, so incorrectly used sometimes in Africa.

Africans are skilled at recognizing plants from their leaves, which must be done in plant recording, for there is no season when all species will be in flower or fruit. Moreover, Africans must not be subjected to ecological theories before they do this recording; so many concepts have been enunciated, accepted, disproved and discarded during the short history of the subject that those at present in fashion are unlikely to last. As I had no training in ecology, I was not exposed to the full impact of the obsolete ideas in vogue when I was a student; but I had much training in soil science and was so indoctrinated with soil erosion that I had been years in Africa before I clearly understood that the grey soils in the valleys were poorer than the red soils on the hills—a pattern which is common in East and West Africa.

Tribal history and legends should be recorded and investigated before they are lost; they may be of more significance than some philosophies, for they do have some connexion with fact. Their examination will facilitate true knowledge of the past, the present and the possible future; for example, the Hamitic people and their cattle moved across Uganda from the north-east about four hundred years ago, which would not be possible at the present time; there must have been open grassland then, with fewer trees, tsetse flies and trypanosomes than there are now. More history and less philosophy are needed for progress in ecological studies in Africa (and, for that matter, in Britain as well). Furthermore, it is far better to leave blank spaces in maps than to fill them in with generalized inferences.

The spectacular increases in yields of cocoa which have followed scientific use of insecticides and fertilizers show that production in Africa need not be limited by 'natural' resources, as is assumed by those whose proposals are limited by ideas of 'conservation'. If there was less abstract discussion, if agriculture was left to the agricultural scientists and farmers, if forestry was left to the foresters, then the conservationists could devote their attention to the problems of wild life, so urgent in Africa. There is more than enough for them to do if the term 'conservation' was altered to 'wild life management' as in America; for the state of some Nature reserves is alarming—the destruction of grass by hippopotamus in the Queen Elizabeth National Park of Uganda and the extermination of trees by elephants in the Murchison Falls National Park.

Africans have adopted from other continents the things which they liked, such as bananas for food, cocoa for cash and football for recreation; they have rejected the things which they did not like, such as some of the labour-wasting methods of farming which have been advocated. Some African practices may seem strange to new-comers, but there is a reason, or there has been a reason, for them. It must not be expected that the

evolution of cultural change will be exactly the same in Africa as in other continents. Those who go to Africa must consider it their duty to learn before they start to teach. "There is all Africa, and her prodigies in us."

NEWS and VIEWS

Deputy Chief Scientific Adviser, Ministry of Defence:
Prof. A. H. Cottrell, F.R.S.

ON June 30, Prof. A. H. Cottrell left the Department of Metallurgy at Cambridge to take up the post of Deputy Chief Scientific Adviser to the Ministry of Defence. This represents the beginning of a new phase in the career of an outstanding scientist who has already made great contributions in the academic and public sectors of science. He was professor of physical metallurgy at the University of Birmingham from 1949 until 1955 and was then appointed deputy head of the Metallurgy Division of the Atomic Energy Research Establishment at Harwell. From there he went to Cambridge in 1958 as Goldsmiths' professor of metallurgy. The interchanges in his career between academic and applied science environments are representative of Prof. Cottrell's attitude to his work. Although he is a first-rate theoretician, he nevertheless has a deep-rooted belief in the importance of applied science. This is revealed in much of his scientific writing, in which theories are developed not as an end in themselves, but as a means of solving the problems which arise when real materials are used in practice. His gift of picking out the essential features of a problem makes his papers and books stimulating reading for first-year undergraduates and research workers alike, and the same quality is evident in his lectures. He was elected a Fellow of the Royal Society in 1955 and, although still only in his middle forties, he has been honoured by many scientific bodies and universities at home and abroad. While at Cambridge he devoted himself wholeheartedly to both teaching and research, and the results will continue to benefit the Department of Metallurgy for many years to come. He will be greatly missed, but Cambridge's loss is the nation's gain since it would indeed be difficult to imagine anyone better equipped to deal with the responsibilities of his new post.

Ministry of Aviation Appointments:

Mr. H. G. R. Robinson, O.B.E.

MR. H. G. R. Robinson has been promoted to deputy chief scientific officer and appointed head of the Instruments and Electrical Engineering Department at the Royal Aircraft Establishment, Farnborough. Mr. Robinson joined the Guided Weapons Department of the Royal Aircraft Establishment in 1948 after graduating with honours in electrical engineering at the Imperial College of Science and Technology. After a year of postgraduate study at California Institute of Technology in 1952, he rejoined the Guided Weapons Department where he was engaged in theoretical and free flight investigation of kinetic heating at very high speeds. This work led, in 1955, to the design of the *Black Knight* re-entry test vehicle, with which Mr. Robinson was directly concerned. In 1960 he became head of the Satellite Launcher Division of Space Department, Royal Aircraft Establishment, and continued in this Department until his present appointment. His main concern in the Space Department was the British technical contribution to the European Launcher Development Organization (E.L.D.O.) launcher *Europa I*, and development of *Black Knight*, for space applications. Mr. Robinson is a Whitworth Scholar, and was awarded the Bronze Medal of the Royal Aeronautical Society in 1960 for furtherance of ballistic missile techniques.

Mr. R. R. Duddy

MR. R. R. Duddy has been promoted to deputy chief scientific officer and appointed director of the *Concord* Project in the Ministry of Aviation. Mr. Duddy was educated at Judd School, Tonbridge, and took a first-class honours degree in mechanical engineering at King's College, London. He first joined the Royal Aircraft Establishment in July 1939 as a vacation student in the Aerodynamics Department, and from 1954 until 1959 he was head of the Flight Division of the Department. He then spent two years with the Defence Research Staff in Washington and returned in 1961 to become head of the Naval Air Department of the Royal Aircraft Establishment at Bedford.

Mathematics in the University of Edinburgh:

Prof. F. F. Bonsall

PROF. F. F. BONSALL, at present professor of pure mathematics in the University of Newcastle upon Tyne, has been appointed to the McLaurin chair of mathematics in the University of Edinburgh as from October 1. Prof. Bonsall was educated at Merton College, Oxford. In 1947, after an undergraduate career which had been interrupted by six years of wartime service in the Royal Engineers, he graduated with first-class honours, and was appointed to a lectureship in mathematics in the University of Edinburgh. He joined the Department of Mathematics in Newcastle as a lecturer in 1948, was promoted to a readership in 1956, and has held the chair of pure mathematics at Newcastle since 1959. Prof. Bonsall has made substantial original contributions in functional analysis. His early work in this field dealt with some of the more algebraic aspects of the theory of Banach algebras. He then became interested in partially ordered vector spaces, a subject on which he is a leading authority. Generalizing a result of Krein and Rutman, he proved that various classes of positive operators possess positive eigenvectors. His work in this area also includes the study of order ideals, related extension theorems for linear functionals, and numerous applications in other branches of analysis. His recent researches deal with the classification of certain semi-algebras of functions, the structure of locally compact semi-algebras, and the further investigation of the spectral properties of positive operators by means of semi-algebra theory.

Industrial Engineering in the University College of Swansea:

Dr. T. O. Jeffries

DR. T. O. JEFFRIES, who has recently been appointed professor of industrial engineering in the University College of Swansea, was educated originally as a physicist, having gained an honours degree in physics from New College, Oxford, in 1947, with a special subject in nuclear physics in 1948. After this he was for three years Faraday Fellow at St. John's College, Oxford, during which time, in addition to his tutorial and lecture duties, he was concerned with the borderline between physics and engineering, participating in the design and construction of the Clarendon Laboratory 400-keV and 1-MeV Cockcroft and Walton accelerators, and completely designing and constructing a smaller 100-keV accelerator to study the D-D reaction. From the Clarendon, Dr. Jeffries moved

to the University of Birmingham as lecturer in physics, where among other work he designed and constructed a propane bubble chamber for use with the 100-MeV proton synchrotron. In 1956 he joined the Atomic Power Division of the English Electric Co., where he worked successively as physicist, mathematician and finally as head of the control and instrumentation group, a department of about 140 engineers, scientists, draughtsmen and technicians. While with the English Electric Co., Dr. Jeffries was responsible for designing and building the *Saturn* analogue computer and the smaller *Mars* computer, as well as for the design and construction of a *Monte Carlo* analogue computer which he used for the shielding calculations on nuclear reactors. During this period, Dr. Jeffries became extremely interested in the application of computers to design problems and to the use of data processing techniques to assist with the design of circuits and in the production of wiring and cabling diagrams.

Inorganic Chemistry in the University of Aberdeen :

Prof. H. F. W. Taylor

DR. H. F. W. TAYLOR took up, on October 1, his appointment as the third professor in the Department of Chemistry of the University of Aberdeen, with special responsibility for inorganic chemistry. Taylor, who hails from Nottingham, studied at University College there, graduating B.Sc. (London) with first-class honours in chemistry; he worked with the late Prof. J. M. Gulland and Dr. (now Prof.) D. O. Jordan on the physical chemistry of nucleic acids—work for which he was awarded a Ph.D. (London) in 1947. On leaving Nottingham he carried out research at Bedford College under Dr. (now Prof.) R. M. Barrer (hydrothermal chemistry of aluminosilicates) and at Birkbeck College under Prof. J. D. Bernal (chemical and crystallographic aspects of the hydration of Portland cement and related topics). For these and later contributions to the chemistry and crystallography of silicates Taylor was awarded the degree of D.Sc. by the University of London in 1957. When appointed lecturer at Aberdeen in 1953 (senior lecturer, 1963) Dr. Taylor continued his studies into the wide field of silicate chemistry especially by the use of X-ray techniques, and he has built up, assisted by Dr. F. Glasser, an active and enthusiastic research team. Investigations are being carried out along two main lines, calcium silicate hydrates and the chemistry of cement hydration—work which gained for him the Mineralogical Society of America Award for 1959, and also on topotactic reactions. His work in these fields is of international repute and he has been invited to take part in and has helped to organize conferences, etc., in Britain, the United States and elsewhere. He is the author of some eighty papers, editor and part author of *Chemistry and Cements*, and co-author with L. Heller of *Crystallographic Data for Calcium Silicates*. Following in the tradition of the Scottish universities, Dr. Taylor has taken, and will continue to take, a great interest in the teaching of the first-year classes. He has found this a challenging problem in both content and method and has introduced, into the practical course, programmed learning, multiple choice testing and the use of the computer for certain types of marking.

Chemistry in the University of Reading

THE years 1965 and 1966 form an important period in the development of the Department of Chemistry in the University of Reading. Now established in one of the largest of the new buildings in Whiteknights Park, the Department will at the end of the session 1965–66 lose the services of its present head, Prof. E. A. Guggenheim, who was appointed professor of chemistry in 1946, having been a member of the Department since 1933. An appointment to a second chair in the Department has already been made; Prof. D. Bryce-Smith, professor of organic chemistry, took up that post in June.

The appointment is now announced of professors in physical and in inorganic chemistry. Dr. G. W. Fowles, who will become professor of inorganic chemistry from January 1, 1966, and Dr. H. M. Frey, who will become professor of physical chemistry from October 1, 1966, are both at present on the staff of the University of Southampton.

Prof. G. W. Fowles

DURING 1943–44 and 1945–46, Dr. Fowles was an analyst in an industrial laboratory, spending the intervening period in H.M. Forces. He entered the University of Bristol in 1946, and in 1949 obtained the degree of B.Sc. with first-class honours in chemistry. He then continued with research and gained his Ph.D. in 1952. Dr. Fowles was awarded the D.Sc. degree in 1964. He was appointed to the Department of Chemistry in the University of Southampton in 1952, where he is now reader in inorganic chemistry. He was Canadian Research Council–Nuffield Foundation visiting professor for 1959 at Laval University, Quebec. He has twice visited the United States, for a Gordon Research Conference and a meeting of the American Chemical Society; and he has spoken at the seventh (1962) and eighth (1964) International Conferences on Co-ordination Compounds. During 1962–65 he was local representative and a member of the Council of the Chemical Society. His research has been concerned mainly with the chemistry of transition metals of the first part of the Periodic Table, although he is also actively working on organometallic compounds of other metals. His present research group is principally concerned with the spectroscopic and magnetic properties of co-ordination compounds of elements of the titanium, vanadium, and chromium sub-groups. He has published numerous papers, and, with E. Cartmell, a book, *Valency and Molecular Structure* (Butterworths, 1956 and 1961).

Prof. H. M. Frey

DR. FREY, after National Service in the Royal Air Force, entered Balliol College, Oxford, in 1949, and in 1951 was University Gibbs scholar in chemistry. He obtained first-class honours in chemistry in 1953, and then became War Memorial student and Imperial Chemical Industries Research Fellow, gaining his D.Phil. in 1955. During 1955–57 he held a Commonwealth Fund Fellowship at the University of California at Berkeley and at Harvard University. In 1957 he was appointed lecturer in the University of Southampton, and has been senior lecturer since 1963. His principal research has been concerned with the elucidation of the features and mechanism of inter- and intra-molecular energy transfer, particularly in relation to unimolecular reactions. Virtually all this work has been in the gas phase, though at present some investigations are being extended to the liquid phase. Much of his recent work has been on highly vibrationally excited molecules formed by methylene addition reactions, or by the photochemical decomposition of diazocompounds and diazirines.

Microbiology in the University of Sussex :

Prof. J. R. Postgate

DR. J. R. POSTGATE, who has been appointed to a chair of microbiology in the University of Sussex, was educated at Kingsbury County School and Balliol College, Oxford, which he entered as a Williams exhibitioner in 1941. He graduated in chemistry with honours in 1945, and found his interest in microbiology when taking his Part II in the field of bacterial growth kinetics under Prof. (now Sir) Cyril Hinshelwood. This interest was developed by a year's study of microbial chemistry under the combined tutorship of the late Prof. D. D. Woods and Prof. A. G. Ogston, and his transformation from chemist to biologist was complete when he took his degree of Ph.D. on bacterial drug resistance under Prof. Woods in 1948. He then joined K. R. Butlin's group

at the Chemical Research Laboratory, Teddington, where he carried out his well-known work on sulphate-reducing bacteria and associated problems in economic microbiology. This work was notable for the discovery of cytochrome c_3 , the first cytochrome to be found in an anaerobic organism, and for developing techniques for handling and studying sulphate-reducing bacteria. This very successful phase of Dr. Postgate's work was abruptly closed by the disbandment of K. R. Sutlin's group in 1959, and Dr. Postgate then undertook and published research on the death of bacteria in conditions of freezing and starvation at the Microbiological Research Establishment, Porton. There he remained until 1963, with an intermission as visiting professor of microbiology in the University of Illinois during 1962-63. In 1963 he joined the Agricultural Research Council to assist Prof. J. Chatt to establish a new Unit of Nitrogen Fixation, now located at the University of Sussex. He will continue to be assistant director of the Unit and his chair is a personal one for the period of his association with the Unit.

Psychology in the University of Newcastle upon Tyne: Prof. J. Brown

DR. J. BROWN has been appointed to the chair of psychology in the University of Newcastle upon Tyne with effect from August 1, 1966. Dr. Brown was born in August 1925. He went to Emmanuel College, Cambridge, graduating B.A. in 1950 after reading the Moral Sciences Tripos. He gained his Ph.D. degree in 1955, and spent three years on research at Cambridge after graduating and then spent one year as a temporary assistant lecturer in the University of Bristol. In 1954 he went to Birkbeck College as assistant lecturer, becoming lecturer in 1956. For the year 1965-66 he has been appointed visiting associate professor in the University of California (Berkeley). His main interests are in perception, learning and remembering, especially problems of immediate memory.

United Nations Review of Space Science

THE United Nations Committee on the Peaceful Uses of Outer Space was formed in 1959, and has served a useful function as the only international governmental body concerned solely with the subject. In 1963 the Committee decided to sponsor a publication describing the activities of the various international and national organizations concerned with space, and this report has now been published by the United Nations under the title *Space Activities and Resources* (Pp. v+172. (A/AC.105/26.) New York: United Nations, 1965. 2 dollars). The report covers first the international governmental organizations which are in some way concerned with space, such as the International Telecommunication Union and the World Meteorological Organization. The next sections describe regional organizations, such as the European Space Research Organization, and non-governmental bodies such as the Committee on Space Research (COSPAR) of the International Council of Scientific Unions. The remainder of the report, about two-thirds of the whole, reviews national space activities. Although the United States and the U.S.S.R. have the largest contributions, there are reports from a total of 37 countries, ranging from Argentina to Yugoslavia, and covering the period up to early 1964. This publication will be welcomed as a work of reference by anyone wishing to sort out the tangled inter-relations between the many international organizations which have decided that space is a subject they cannot afford to ignore. It also provides a useful review of national space activities, especially those of the smaller countries, which are little publicized.

Molecular Pharmacology

THE first reaction of a scientific reader to a new journal is one of alarm: he has already to look at too many of them

and his absorptive capacity is limited. Moreover, the title of the recently issued *Molecular Pharmacology* is really a tautology. Pharmacology is the science of the examination of the interaction of organic and inorganic molecules with living matter. It follows that all pharmacology is molecular. However, much can be said in defence of this new journal (1, No. 1, July, 1965. Edited by Avram Goldstein. Pp. 1-112. New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965. Subscription rates: Vol. 1, 1965, 3 issues—International subscribers, 11 dollars; Private subscribers certifying that the journal is for personal use only, 5 dollars). It is being launched under the auspices of the American Society for Pharmacology and Experimental Therapeutics, which is also responsible for the well-known *Journal of Pharmacology and Experimental Therapeutics*, a publication that carries much material of immediate interest also to the physiologist and clinician. The need may have been felt for a paper that appeals more to the reader whose interests lie mainly in the theoretical aspects of pharmacology. A glance at the first issue shows that it is mainly the development of modern biochemistry (and biophysics) that has made this new venture necessary. The study of enzymes, of proteins in general, of nucleic acids, of cell particles and of cell membranes makes up the main content, and there is also material that deals with transport, with receptor theory and with the genetic code. *Molecular Pharmacology* carries the sub-title "An International Journal". The members of the advisory board and of the editorial board include scientists from many lands, well known to all workers in this field. The editor is Dr. Avram Goldstein, of Stanford University Medical School. We wish him success in this new enterprise.

Use of CIBA Resins in Ireland

THE growth potential in the use of synthetic resins and ancillary products in rapidly expanding industries both in Ulster and in the Republic of Ireland has been recognized, since the beginning of 1965, by the establishment by Ciba (A.R.L.), Ltd., Duxford, Cambridge, of an office and distributing depot in Belfast. Some details of actual developments involving the use of the well-known 'Aerolite' and 'Araldite' products in blockboard and paint manufactures, for example, are given in a recent issue of *Technical Notes*, entitled "Ciba Resins in Ireland" (Pp. 8. Ciba (A.R.L.), Ltd., Duxford, Cambridge. June 1965). In Northern Ireland there has been, in recent years, a notable expansion in the building industry, especially concerning prefabricated units. One example is the manufacture of wood chipboard, involving the use of large quantities of 'Aerolite' resin each week, at the factory of the Ulster Chipboard Company at Coleraine, County Londonderry; in this case the raw material is forest thinnings from timber felled from three of the largest forests in Northern Ireland; the process consists of coating the wood chips with resin, pressing the boards, then sanding on both sides to specified thickness. Other firms using 'Aerolite' adhesive are in large-scale production of such items as panel doors, flush doors, casement windows, garage doors, staircases, school and church furniture. In Eire, similar activities and modern trends in prefabricated timbers are briefly described. In the factories of T. and C. Martin, Ltd., Dublin, a finger-jointing machine produces continuous lengths of jointed timber by gluing selected raw timber of relatively short length with 'Aerodux 500' resorcinol resin adhesive, clamping and pressing, then cutting automatically to the desired length; timbers jointed in this way are eminently suitable as laminated members for structural engineering. Among paint manufacturers, Syntheses, Ltd., Dublin, use 'Araldite' epoxy resin formulations in their production of high-duty paints demanding good mechanical and chemical resistant properties. A further example of this is quoted in the case of Kosangas, Ltd., Dublin, suppliers of

R342

gases in steel bottles—containers which are subject to hard use; they are successfully coated with 'Araldite'-based paint, after shot-blasting, applied by electrostatic spray. These Ciba resins are being increasingly used by other industries in Ireland and such uses are planned for description in forthcoming issues of *Technical Notes*.

Iron Ore Production and Research at Broken Hill, Australia

THE well-known *B.H.P. Technical Bulletin*, produced periodically by the Broken Hill Proprietary Co., Ltd., Australia, is always a source of valuable technical information on the iron ore industry, arising from operational and research activities within this great organization, and the issue published in April 1965 is no exception to this dictum (No. 22: 9, No. 1; April 1965). An important contribution is a series of articles describing a new ore agglomeration laboratory built at the Company's Central Research Laboratories at Shortland, New South Wales. A general description of the new premises is first given by L. C. Bogan, who describes the laboratory layout, technological capabilities and limitations of the pilot plants installed, programmes scheduled, and services available; the latter includes chemical analysis by direct-reading spectrophotometry, petrology, and X-ray diffraction and X-ray spectroscopy. "Comminution and Green Pellet Production" is the title of a second article, by D. H. Harraway, in which he discusses the several pilot plant operations involved in production of green pellet agglomerates, comminution of the ore and mixing it with additives and water to form the ore pellets. A third article, "The Experimental Pellet Heat-Hardening Unit", by C. W. Brock, describes how, having produced the green pellets, it is necessary to heat-treat them "... to form a strong, approximately spherical aggregate capable of withstanding weathering and the high handling stresses which may be expected in stockpiling, transportation and blast furnace charging". Further contributions to this *Bulletin* include an account of "The Development of Koolan Island", by M. T. Phillips; this is one of the islands of the Yampi group off the north-west coast of Australia, where production of iron ore commenced in 1964. Petrological research is represented by an interesting paper by Sylvia Whitehead entitled "Petrological Notes on the Koolyanobbing Iron Ore Formation", the location being the Koolyanobbing range of hills situated about 35 miles north-east of Southern Cross, Western Australia. An important haematite ore-producing region in South Australia is the Middleback Ranges, and K. L. Ashworth describes this and other prospects in his article on "Geology of Iron Duke, South Australia", situated approximately 36 miles west of Whyalla, on the eastern Eyre peninsula. Finally, there is a paper by J. A. Gregory and S. Wolski on "Experimental Assessment of Factors Controlling the Production of High-Basicity Sinter".

South African Prehistory

AN interesting pamphlet entitled *Bowmen, Spears and Shields in Southern Rhodesian Rock Art*, concerned with the types of shield depicted by the artists and the distribution of the bowmen and the spears, has recently been published (*Cimbebasia—SWA Research*, No. 10. Pp. 8. Windhoek, S.W.A.: State Museum, 1964). The author, C. K. Cooke, has personally visited more than a thousand rock shelter and cave sites and has, of course, drawn on the works of other authorities. The important fact which emerges is that the shields figured are of definitely Bantu type, and this would suggest that many of the painted rock shelters must be A.D. in date. It has been the custom to ascribe a great antiquity to the rock paintings of Southern Rhodesia and South Africa. However, it has constantly been forgotten that paintings in open rock shelters could scarcely have survived serious climatic changes, such as have occurred in the distant past

—conditions which permitted much precipitation and subsequent evaporation of water vapour on the rock shelter walls. It is therefore very interesting that research into the types of shield figured in this late phase of Southern Rhodesian rock art points to a comparatively late date for its creation. The late C. van Riet Lowe once remarked that the celebrated "White Lady" of Brandberg could as well have been painted in A.D. 1500 as in 1500 B.C. The June issue of the *South African Journal of Science* contains an interesting article by R. R. Inskeep. Not far from Port Elizabeth a series of springs on the hillside behind the homestead on the Amanzi Estates has deposited thick sediments which contain many lower palaeolithic implements. The author has undertaken some considerable excavation and gives us geological sections and a determined stratigraphy. The implements are almost all of the core type, though some worked flakes do occur. Hand-axes, cleavers and choppers have been collected, and the author dates the finds to an early stage in the Old Stone Age. Some samples of pollen were noted, and tentative identifications indicate the presence of members of the Cyperaceae, Gramineae, Compositae and Leguminosae (including an acacia) families. Mr. Inskeep is to be congratulated on a useful piece of work.

Bark Canoes and Skin Boats of North America

LIKE many traditional crafts, the building of bark canoes is dying out and much information about it has already been lost. E. T. Adney, who died in 1950, was a skilled artist, who devoted a good deal of his life to the study of these canoes and acquired practical experience of building them. He left a lot of models, now in the Mariner's Museum at Newport News, Virginia, as well as numerous papers "in a highly chaotic state". H. I. Chappelle, who is curator of transportation in the Museum of History and Technology, a constituent of the U.S. National Museum, has carried out the arduous task of compiling the relevant information from these papers and the models (Smithsonian Institution, Washington. Museum of History and Technology. Bulletin No. 230: *The Bark Canoes and Skin Boats of North America*. Pp. xiv + 242. Washington, D.C.: Government Printing Office, 1964. 3.25 dollars). He has added a chapter on Arctic skin boats and one on temporary craft—canoes of bark other than birch, moose-hide boats and the coracle-like bull boats. There is an appendix on rolling kayaks by J. D. Heath. Information derived from Adney makes up the main part of the book. It consists of three chapters on early history, materials and tools, and form and methods of construction, followed by three chapters treating in detail the canoes of the Eastern Maritime Region, Central Canada, and North-West Canada, of which the first is the fullest. The work is fully illustrated with photographs from many sources and excellent drawings, mostly redrawn from Adney's by Chappelle. Amid a wealth of detailed information a fact of general interest emerges. There is a fundamental difference between bark canoes and Eskimo skin boats, namely that the frame of the bark canoe (and this includes 'temporary' Indian skin boats) is built up within the cover and would collapse without it, whereas the Eskimo boats have a rigid frame over which the skin cover is afterwards stretched. As is well known, bark canoes are so suitable for their purpose that they were at once adopted by Europeans on arrival, and used on a large scale in the fur trade. This suggests that this valuable publication may find a practical use in addition to its great historical importance.

Production Ecology in Tropical High Forest

NOT much work has been carried out on production ecology in tropical high forest although it is estimated that 38 per cent of the forests of the world belong to this type. However, a very useful investigation has been carried out in the southern Ivory Coast (*Production*

Brute, Pertes par Respiration et Production Nette dans la Forêt Ombrophile Tropicale. Par D. Müller et Jørgen Nielsen. Pp. 69-160, illus. *Det. Forstlige Forsøgsvaesen*. Denmark, 1965). Field measurements were made in 1955, 1957 and 1960, in two sample plots measuring 30 m × 30 m and 40 m × 40 m. Altogether there were 209 trees of more than 3 cm diameter breast height but 58 per cent belonged to 5 of the 45 species represented. All the trees in the smaller plot were felled after the 1955 measurements, care being taken first to clean a sufficient area so that the entire crowns fell on places where it was possible to collect all the leaves from the sample trees. In the larger plot basal areas, form factors, volumes and current annual increments were calculated from diameter and height measurements. Other data provided statistics for the branch percentage, loss of dry matter by respiration, surface area and weight of leaves, leaf-fall and photosynthetic efficiency. Special attention is given to the occurrence of 'light' leaves and 'shade' leaves which is a characteristic shared by deciduous trees of temperate and tropical forests, but dominants in the latter tend to have 'light' leaves only and it is suggested that this is why their crowns are usually small. In this particular example the net production of dry matter came to 9.0 metric tons per hectare per annum (roots, stems and branches) but the gross production was 52.5 metric tons per hectare per annum. It is interesting to note that although the production of dry matter is only very slightly less than for an even-aged beech forest in Denmark, the gross production is more than twice. Indeed, it is a characteristic of lowland tropical high forest that there is a large gross production and a great loss of dry matter by respiration in the stem, branches and leaves. This is a most welcome contribution to the subject of production ecology and the authors have provided useful data. Perhaps the exercise also demonstrates the difficulty of taking an adequate sample in tropical high forest and yet keeping the work within the realm of practical possibility. For example, familiar dominants of the tropical high forest of West Africa are absent from the tree lists given. In the smaller plot, the second largest tree by diameter (63.6 cm) and in height (27 m) is *Turraecanthus africanus*, which is not a typical emergent of this forest. The tallest tree recorded from both plots is 50.2 m and only two others reach 40 m or more.

Elementary Particle Physics

FOLLOWING the review of *Group Theoretical Concepts and Methods in Elementary Particle Physics* (*Nature*, 207, 118; 1965), Messrs. Gordon and Breach, Science Publishers, Inc., have written to the Editor, stating that two prices are available for this book. There is a professional edition published at 14.50 dollars, and a reference edition published at 21.50 dollars.

Announcements

THE Wellcome Laboratories of Tropical Medicine which since 1934 have been housed in the Wellcome Building, Euston Road, London, have moved to new laboratories on the site of the Wellcome Research Laboratories at Langley Court, Beckenham, Kent.

WITH the July 1965 issue, the *Bulletin of the Libraries of Commerce, Science and Technology* of the Sheffield City Libraries takes a new style and arrangement (No. 1, July 1965. Pp. 18. Sheffield: Sheffield City Libraries, 1965). While continuing to notify accessions, with the exception of some pamphlets and miscellaneous material, the *Bulletin* will now announce any developments within the libraries affecting readers and users of their services. The present issue includes a list of directories and also a list of recent metallurgical reports.

OPEN days will be held at the Tropical Products Institute during October 14-15. Further information can be

obtained from the Director, Tropical Products Institute, 56-62 Gray's Inn Road, London, W.C.1.

A CONFERENCE on "Technology and Society" will be held in Bath during October 14-16. Further information can be obtained from Mr. J. H. Lamble, Bristol College of Science and Technology, Ashley Down, Bristol 7.

THE third INTERKAMA Exhibition and Congress will be held in Düsseldorf during October 13-19. Further information can be obtained from Nordwestdeutsche Ausstellungs- und Messe-Gesellschaft m.b.H., 4 Düsseldorf 10, Postfach 10203.

THE Arthur Stanley Eddington Memorial Lecture for 1965, entitled "The Brain and the Unity of Conscious Experience", will be delivered by Sir John Eccles in Cambridge on October 15. Further information can be obtained from W. B. Harland, Sedgwick Museum, Cambridge.

A SYMPOSIUM on "The Future Pattern of Research in Instrument Technology", arranged by the Tees-Side Section of the Society of Instrument Technology, will be held at Middlesbrough on October 14. Further information can be obtained from Mr. G. F. Shute, 10 Mayberry Grove, Linthorpe, Middlesbrough, Yorkshire.

THE ninth conference on "Analytical Chemistry in Nuclear Technology", sponsored by the Analytical Chemistry Division of the Oak Ridge National Laboratory, will be held in Gatlinburg, Tennessee, during October 12-14. Further information can be obtained from C. D. Susano, Oak Ridge National Laboratory, P.O. Box X, Oak Ridge, Tennessee 37831.

AN international conference on "Dynamic Stability of Structures", sponsored jointly by the U.S. Air Force Office of Scientific Research and Northwestern University, will be held in Evanston, Illinois, during October 18-20. Further information can be obtained from Prof. George Herrmann, Technological Institute, Northwestern University, Evanston, Illinois.

THE annual meeting of the Conference on Electrical Insulation of the National Academy of Sciences-National Research Council will be held at Buck Hill Falls, Pennsylvania, during October 25-27. Further information can be obtained from Mr. D. W. Thornhill, Conference on Electrical Insulation, National Academy of Sciences, 2101 Constitution Avenue, N.W., Washington, D.C.

CORRIGENDUM. In the article entitled "Environmental Determination of Insular Variation in Bird Species Abundance in the Gulf of Guinea" by Prof. T. H. Hamilton and N. E. Armstrong, which appeared on p. 148 of the July 10, 1965, issue of *Nature*, the following corrections should be made: (1) Second paragraph, line after equation (4) should read: "where $z \neq 1$ " (not ' $x \neq 1$ '). (2) Third paragraph, thirteenth line, should read: "estimate the radius . . . as 7.25 miles" (not '. . . as 7 . . .'). (3) Third paragraph, seventeenth line, should read:

$$". . . \pi r \sqrt{r^2 + h^2}" \text{ (not } '\pi r \sqrt{r^2 - h^2} \text{').}$$

CORRIGENDUM. In the communication entitled "Radiochemical Determination of the Endogenous and Exogenous Respiration of Bacterial Spores" by H. Desser and Prof. E. Broda, which appeared on p. 1270 of the June 19, 1965, issue of *Nature*, line 33 should read ". . . The specific activities were up to 6.6×10^3 ". Also, H. Desser and Prof. E. Broda thank Prof. H. O. Halvorson, Madison, for the gift of *Bacillus cereus* and for advice on its cultivation.

ERRATUM. In the communication entitled "Benzene-sulphonylcarbamates: New Herbicides" by Helen J. Cottrell and Dr. B. J. Heywood, which was published on p. 655 of the August 7, 1965, issue of *Nature*, the first reference should read as follows:

¹ Carpenter, K., Heywood, B. J., Parnell, E. W., Boesch, R., and Metivier, J., Brit. Pat. Appln. 32407/62, and Brit. Pat. Appln. 8805/63.

FUEL POLICY FOR BRITAIN

ON January 22, 1965, Mr. F. Lee, the Minister of Power, told the House of Commons that he was undertaking a general review of fuel policy and had already initiated discussions with the chairman of the nationalized fuel industries. To assist consultation on a wider basis he was setting up an Energy Advisory Council. This Council would consider and advise him about the energy situation and outlook, and about plans and policies of the fuel and power industries in relation to national objectives for economic growth. At the end of June he told the British Electrical Power Convention at Brighton that he expected the results of this review of fuel policy to be ready soon. At the same time, he asked the industry to increase capacity to the point where reasonable, but not excessive margins, were secured. Moreover, he asked the industry to do this for the lowest practical demands on real resources and a very substantial use of self-generated funds, absorbing wherever possible the increases in operating costs so that prices to consumers remained stable. Concerning co-operation between the nationalized fuel and power industries in research and development, Mr. Lee said in the House of Commons on July 13 that he had already approached the industries; the National Coal Board and the Central Electricity Generating Board had for some time had a research liaison committee. The Gas Council had now joined with them to form a joint Liaison Committee for research and development so that their scientific potential might be used to the fullest advantage. The primary, though not the exclusive, objective was to improve the technology of utilizing coal. Mr. Lee said that the research programmes of the three industries were extensive, but he was bringing them into closer co-operation.

In view of all this a Broadsheet, *Questions of Fuel Policy*, issued by Political and Economic Planning*, is of some special interest. The Broadsheet starts by comparing the terms of reference of the Energy Advisory Council with the instructions given to the Ridley Committee on National Policy for the Use of Fuel and Power Resources when it was established in 1951. It points out that any recommendations the new Council may be able to agree on as to national policy are likely to represent, at the best, the highest common factor of agreement between existing vested interests. The Ridley Committee, on the other hand, was an independent group of public men, economists and technologists, examining the fuel industries rather than representing them, and was more likely to be free to formulate fresh policy in a way that the new Energy Advisory Council could not be expected to do. This in itself makes the independent review in this Broadsheet of the greater interest, although it must be admitted that in practice the advice of the Ridley Committee was not taken very seriously.

The Broadsheet notes that in 1964 Britain used primary energy equivalent to about 285 million tons of coal. Of this total about 187 million tons was actually coal; petroleum products accounted for about 93 million tons of coal equivalent, of which some 30 million tons was road- or air-transport fuel or used in refineries. Of the remaining general fuel used, coal accounted for nearly three-quarters compared with nearly 90 per cent in 1951. In absolute terms, coal consumption in 1964 was 20 million tons less than in 1951. Over the same period, the consumption of oil as a general fuel rose about five times to some 55 million tons. So far as total fuel consumption is concerned, the forecasts of the Ridley Committee in 1952 for fuel consumption during the

period 1959-63 were fairly well confirmed (coal providing however, only some 70 per cent of the total instead of 95 per cent, as forecast). Apart from the switch to oil there has been a further decline in the direct use of coal and more and more of the final consumption of this fuel is now in the form of electricity.

On the framework of present-day policy, P.E.P. points out that imports of coal are subject to licensing and in practice no licences are granted; moreover, import licences have not been granted for any increased imports of Russian oil. Since 1961 a fairly high excise duty of almost £2 a ton has been imposed on fuel oil and other oil products sold in the general energy market, while some restraint has at times been placed on the development of electricity generation from oil. Nuclear energy constitutes another factor and the Government has also abolished the customs duty on methane, which has slightly improved the economics of the scheme for importing liquefied natural gas from Algeria.

Considering new factors in the forecasts for the consumption of fuel, the Broadsheet points out that the forecasts and investment programmes of the major fuel industries represent, even over the short term, a higher total fuel consumption than is generally forecast—as has been pointed out by the National Economic Development Council. Forecasting demand for fuels is fairly hazardous in the commercial or technical sense beyond the 7-10 year period affected by decisions regarding investment that must be taken in the next 2-3 years. Petroleum exploration in the North Sea is particularly hazardous, and however welcome might be the impact of North Sea gas to upset established forecasts, it may not be an economic proposition. A more practical factor in present calculations is the firmer offer of cheap nuclear power. The rapid downward revision of nuclear costs could mean a much higher rate of commissioning of nuclear plant in the construction programmes of the supply industry by 1975 than has so far been envisaged, and in consequence an earlier levelling off in the demand for coal by power stations.

A working group of P.E.P. which is considering the energy situation and the kind of national fuel policy most suitable for Britain in the 'sixties expects to publish a full-scale report by the autumn of 1965. In the meantime, the Broadsheet indicates some of the problems which must face those responsible for formulating policy in this field. First, it points out there is the question of whether fiscal policies, such as the levying of a fuel tax on oil used in power but not on oil used in gas manufacture, should be altered so as to favour gas less. Alternatively, should gas be assisted to take over more of the demand for space heating and electricity discouraged in this sector of the domestic market? Again, there is the question of whether Ministerial policy should attempt to settle the constantly vexed arguments between the two industries and their cross-accusations about the special financial incentives alleged to be offered to local authorities and other housing developers. Again, is the right balance between amenity and efficiency being struck at present in the lengthy procedure of licensing, public enquiry and the like required for the construction of electricity production and transmission equipment? Some might also be disposed to ask whether the present structure of Government is such as to enable amenity issues to be raised at a sufficiently early stage for full effect to be given to their arguments before the electricity authorities are committed to particular schemes. Another important question is whether research and development are adequately and properly organized in these industries,

* *Planning*, 31, No. 489 (June 1965): *Questions of Fuel Policy*. Pp. 183-218 (London: Political and Economic Planning, 1965) 6s.

and in particular whether the balance of activity and initiative in nuclear development between the Central Electricity Generating Board and the Atomic Energy Authority is correct. Here again questions of Government structure may also arise, particularly in respect of the position of the Ministry of Technology.

Other questions suggested for consideration in the Broadsheet are the structural division of electricity supply for England and Wales and for Scotland, and whether there is scope for forms of combined technical development between the industries, and possibly coal or oil also, that are being ignored at present because of the structural separation and competition. The Broadsheet also questions whether limits should be put to commercially competitive promotion between the nationalized fuel industries, and how far they should be obliged to keep their investment policies with the Government's forecasts of solid and other smokeless fuel requirements arising from application of the Clean Air Policy. The principles to be followed in permitting these nationalized industries to diversify their activities in the fields outside those in which they now operate also require definition. The Broadsheet hints plainly that the consumer is not at present adequately informed of the price trends in the various fuels. The present structure of the Ministry of Power also requires consideration in the context of

how far it conduces to a sensible co-ordination of national energy policy and to objective assessments of conflicts of policy between the nationalized fuel industries.

It should also be remembered that some of the technological changes that could occur in the supply of energy would bring with them new questions about the structure of the British fuel industries. For example, if large-scale natural gas-fields were in fact found in the North Sea, the present gas industry, with its virtual monopoly and its commitment to manufacture gas at lower calorific values, might not be the ideal instrument to introduce the natural gas into the British market. Possibly a measure of competition should be introduced when gas supply becomes more and more based on the end-products of oil refining. Nor should it be without due consideration whether the economies of scale in supply or in transmission are as compelling, or whether monopoly is as appropriate a form of organization for gas as for electricity supply. The Broadsheet offers no answers to these problems, but it does suggest that urgent public consideration should be given to them and particularly to the determination of the right order of priorities. This is especially so in regard to what protection the fuel industry should receive, particularly British coal, and in what form.

U.S. STANDARD FREQUENCY AND TIME SERVICES

A REVISED (1965) publication of the United States National Bureau of Standards* gives a detailed and illustrated description of the services provided by the Standard Frequency Stations now operating in Washington, Hawaii and Colorado. The first is the well-known station, *WWV*, at Greenbelt, Maryland, which has been in operation since 1933, and now provides services of radio and audio frequencies, musical pitch, time signals and the departure of these from astronomical time; propagation forecasts and geophysical alerts are also issued from *WWV*. An additional service was started from Hawaii in 1948; but this is confined to radio frequencies, time signals and their corrections. In 1963, two low-frequency transmissions were added from stations at Fort Collins, Colorado. One, *WWVB*, broadcasts continuously on the standard frequency of 60 kc/s, and provides time signals and corrections, while the other, *WWVL*, broadcasts continuously on the standard frequency of 20 kc/s. The frequencies of all these services are held stable in general to a few parts in 10^{11} , and they are ultimately referred to the resonance frequency of caesium, which is measured in terms of ephemeris time.

All the carrier and modulation frequencies at *WWV* and *WWVB* are derived from precision quartz oscillators of

* United States Department of Commerce: National Bureau of Standards. Miscellaneous Publication 238: *Standard Frequencies and Time Services of the National Bureau of Standards*. Pp. 8. (Washington, D.C.: Government Printing Office, 1965.) 15 cents.

high stability. These are offset from the standard by a small but precisely known amount to reduce departure between the time signals as broadcast and astronomical time, U.T.2. Although the latter is subject to unpredictable changes readily noted at this level of precision, it is expected that the present offset—150 parts in 10^{10} —established in 1964, will remain in effect for the present calendar year (1965). For the benefit of users who wish to make direct comparisons of absolute frequencies, *WWVB* has been transmitting on 60 kc/s with no offset since January 1, 1965.

A comprehensive description, with diagrams, of all these services is given in the report, together with details of the propagation forecasts and geophysical alerts which are disseminated at hourly intervals. The forecast announcement tells users, in a simple code form, the condition of the ionosphere at the regular time of issue, and the quality of radio services due to propagation conditions to be expected during the next 6 h. A series of letter symbols is used to indicate the current geophysical conditions and give notice of any outstanding solar or geophysical events which are expected or which have occurred in the preceding 24 h.

The revised issue of this publication will be welcomed by all users of frequencies and time signals, as well as by research workers in the fields of radio and the geophysical and solar sciences.

R. L. SMITH-ROSE

COMMERCIAL NUCLEAR POWER STATIONS IN BRITAIN

THE principal contents of the July number of the *Journal of the British Nuclear Energy Society* (4, No. 3; 1965) consists of the texts of the six papers contributed by members of the Central Electricity Generating Board and the South of Scotland Electricity Board and presented to the symposium on the performance of commercial nuclear power stations in the United Kingdom, which was held at the University of Leicester on June 30.

H. M. Carruthers, in his discussion of the evolution of magnox station design, points out that, in the nine years since the first Calder Hall reactor went critical, some

thirty-five reactors of this basic type have been built, of which twenty-six are in Great Britain. The reactors during this period have developed from a small unit of about 40 MW(e) output to one of nearly 600 MW(e) with at the same time reduced capital and generating costs. The main technical improvements in layout, shielding, refuelling methods, pressure circuit technology and fuel element design since the start of the commercial magnox programme are described in some detail.

The commissioning of a nuclear power station requires not only the setting of the plant to work safely and

reliably, but also at the minimum cost computed over the total life of the station. The history of the commissioning of the Berkeley and Bradwell stations is reviewed by C. D. Heath and D. J. Silverlead, and in their assessment they direct attention to the need for greater flexibility in the timing of the various tests and measurements, improvements in the planning of construction and plant installation, and some simpler form of commissioning organization.

Two papers deal with the performance of reactor cores and materials and of power station plant, and a third with power station maintenance. Of the nine civil nuclear stations, Berkeley and Bradwell have had more than two years' full-power operation and Hunterston one year. Serious defects have been experienced at all three stations and the extra fuel costs have amounted to about six and a half million pounds. The major defects were in the fuelling routes, turbines and boilers. Experience suggests that more reliable operation in the future will occur. With

regard to maintenance, it is emphasized that health physics requirements are an important factor in maintenance planning and that future stations should be better planned and equipped for the maintenance of radioactive equipment.

The final paper in the symposium, by P. H. G. Holbrook and A. C. Horne, deals with some of the special problems, not necessarily technical, which arise in the operation of a nuclear power station. The provisions of the Nuclear Installations Licensing and Insurance Act, 1959, the Radioactive Substances Act, 1960, and the Generating Board's safety regulations have to be enforced and accordingly appropriate inspectorates and organizations have to be established. The increased automation of future stations, with centralized control and computational operation, may lead to a change in the pattern of station organization with economies in technical man-power and less risk to personnel.

S. WEINTROUB

PHYSICS EDUCATION

IDEALISM and iconoclasm were offered in equal proportions by speakers at the International Conference on the Education of Professional Physicists, held in London during July 15-21. The meeting was arranged by the Institute of Physics and the Physical Society for the International Union of Pure and Applied Physics, and attracted participants from twenty-five countries.

Lord Beeching (Imperial Chemical Industries, Ltd.), in a forthright introductory speech, deplored the attitude of university departments which, while disclaiming interest in vocational training, were in fact preparing students exclusively for the vocation of fundamental research. It was, he asserted, not in the public interest that academic research should be presented as the best career for physicists at a time when the industrial, economic and political problems of the community were increasingly dependent on the widespread use of science and technology. Though the Government had great responsibilities in the deployment of scientific and technical resources, only a handful of Junior Ministers had any scientific training. The cause of this deficiency was in the attitude which asked: "Why should we train a good physicist, only to have him wasted as a politician?"

Students of physics must learn that they were not going to be employed exclusively in the narrow practice of their specialty, Lord Beeching continued. Many graduates would find careers in which knowledge of physics was only a small part of the requirement. His own company employed 290 physicists, of whom half held posts not necessarily filled by physicists and about 10 per cent were doing work for which scientific qualifications were not essential. The object of the Government and the universities should be to create an apparent surplus of scientists, many of whom would move into management, administration and politics.

Most of the subsequent contributors were concerned with the scope and content of the undergraduate curriculum, but there was lively discussion also on the extent to which industry's needs were fulfilled by the products of the universities.

A discussion of the young physicist's training and progress in industry, offered by G. S. Bosworth (English Electric Co., Ltd.), was strongly criticized by A. B. Pippard (Cavendish Laboratory, Cambridge) as showing how second- or third-class people could be turned into useful members of an industrial team, while offering nothing to attract the first-class scientists who were badly needed in British industry but were repelled by the Philistine attitude of prospective employers.

Extreme differences of opinion such as this were infrequent. It was generally recognized that the primary

purpose of a university was the advancement of learning and that an industrial concern would fail unless it was conducted to make a profit. Efforts to secure closer collaboration between the university and the industrial community in undergraduate and postgraduate work were reported from several parts of the world; it was agreed that physicists were somewhat better prepared for a practical career in countries such as Holland, where industrial scientists and engineers had a substantial role in academic research and teaching.

Discussion of the content of the curriculum embraced three main topics: (a) mathematics, (b) laboratory work, and (c) lectures. Commenting on the importance of adequate mathematical training, M. Y. Bernard (Conservatoire National des Arts et Métiers, Paris) proposed, not entirely in jest, that special courses should be provided for university teachers of physics, who might otherwise be embarrassed by the superior mathematical ability of their students. The consensus of opinion in France, he reported, called for three kinds of instruction. Professional mathematicians should be responsible for about 25 per cent of the undergraduate's course, dealing with topics where a rigidly logical approach was valid. A physicist should have about 40 per cent of the available time, to cover inductive methods and the development of general laws. The rest of the course should be devoted to exercise classes.

More radical views were asserted by Bernard Friedman (University of California), who condemned the "pernicious influence of sound old-fashioned courses in classical mathematical physics". Up to the end of the nineteenth century, he said, important problems giving insight into the physical world were tackled and solved by the use of special functions, separation of variables and often complicated techniques of integration. These methods were now out of date, partly because of the increasing mathematical sophistication of modern physics and partly because of the rapid advance in electronic computing. When numerical results were required, the computer would generally give more accurate results with less effort. If, on the other hand, a qualitative approach was attempted, mathematical techniques of a more abstract kind were now available.

To understand the mathematical content of present-day physics, the student must be trained in linear algebra, probability and Markoff processes, functional analysis, group representations and Lie algebras. Time does not allow the prospective physicist to follow the standard mathematical courses on these topics, but a briefer curriculum must not be allowed to degenerate into a collection of recipes for solving standard types of problem. Emphasis

should be put on the teaching of abstract concepts such as linear spaces, linear operators, convergence in metric spaces and group invariances and symmetries, even if the immediate practical applications were not fully described.

Comments on practical work were remarkable for the diversity of ideas revealed. S. C. Brown (Massachusetts Institute of Technology) claimed that the main object was to teach what a physicist does. Systematic experiments and laboratory reports should therefore be abandoned in favour of project work, closely linked with the research programme of the department. It was suggested that only the 2,000 physics students at Massachusetts Institute of Technology could ever enjoy such lavish attention, but Brown reported that most of the forward-looking universities in the United States used the same method. Some speakers thought that practical physics could be taught in lectures, though manipulative skill could only be acquired by experience at the bench. E. Mendoza (University of Wales) and F. H. Read (University of Manchester) favoured seminars in which a class (of up to fifty students) conducted one experiment under the guidance of a lecturer.

However great the importance of mathematical and practical instruction, the core of the undergraduate cur-

riculum is in the systematic lectures by which the principles and applications of the subject are uncovered. The burdens laid on the undergraduate's knowledge and on his maturity of understanding are augmented every year. A. B. Pippard showed, from a study of examination papers, how to-day's student is expected to know just as much about electricity, thermodynamics and other long-established divisions of physics as his counterpart of 1940—and in addition, to be conversant with many newer topics of a substantial kind. His solution was to reduce the first-degree course to two years and to provide a more comprehensive training for a proportion of the student body.

The conference passed a number of resolutions of an unexciting character, but its real significance was based on divergence rather than unanimity. Physicists are produced with evident success in educational systems sufficiently varied to include strict Government control of priorities and syllabuses in the U.S.S.R., unfettered academic enterprise in the United States and the amalgam of tradition and innovation characteristic of both the older and newer British universities. The competence and enthusiasm of the finished products encourage the belief that the confusion over aims and methods is superficial.

J. M. A. LENIHAN

PLANT PHYSIOLOGY IN CANADA

THE annual scientific and business meeting of the Canadian Society of Plant Physiologists—La Société Canadienne de Physiologie Végétale—was held at the University of New Brunswick, Fredericton, during June 2-5.

The programme commenced with a symposium entitled "Problems in Marine Algal Physiology". J. S. Craigie (N.R.C., Halifax) discussed the problems of isolating and identifying marine algal excretory products from sea-water. Compounds excreted by several brown and red algae were identified as condensed polyphenolic substances with distinct growth-promoting properties. A brominated benzyl alcohol derivative excreted by *Polysiphonia lanosa* was isolated and crystallized. A pure crystalline extracellular chitin excreted by the diatom *Thalassiosira fluviatilis* was isolated and characterized and was claimed to be the first recorded evidence for the occurrence of poly-*N*-acetyl glucosamine in the algae. L. Provasoli (Haskins Laboratories, New York) discussed the nutritional requirements of marine algae grown aseptically. Unlike unicellular algae, seaweeds grown autotrophically require a range of vitamins in specific concentrations and ratios for normal morphological development. The growth of *Ulva* and *Monostroma* in aseptic culture was maintained only in the presence of plant hormones, phenolic compounds, and by the addition of supernatants containing active substances from a variety of red and brown seaweeds and from several unicellular algae grown aseptically on artificial media. These unidentified active substances are ethanol extractable and heat resistant and their ubiquitous production in the sea underlies the significance of external metabolites in the water environment. R. T. Wilce (Amherst, Massachusetts) discussed algal survival in the Arctic Sea. Reproductive activity at the end of the winter period and an abundant spring and summer growth were found to depths of 30 metres. The greatest concentration of algal biomass occurred at 15-20 metres, where extremely low light intensities were recorded. Survival under these conditions requires either the possession of a highly efficient photosynthetic apparatus or the facility to exist heterotrophically. Evidence for the heterotrophic growth of pigmented algae in deep lakes and unlit caves suggested

that these arctic populations also thrived by the heterotrophic utilization of organics from the sea.

Several scientific sessions followed the symposium. Continuing their work on plant photorespiration, G. Krotkov *et al.* (Queers, Kingston) showed a distinction in spruce tissue between photo- and dark-respiration with the latter inhibited by light. W. Turner and R. G. S. Bidwell (Toronto) presented evidence for the enhancement of assimilation of carbon dioxide by leaf blades with application of IAA. E. R. Waygood *et al.* (Manitoba), working with detached wheat leaves, showed that photo-phosphorylation could be both restored and enhanced by benzimidazole treatment and that the synthetic pathway of NAD and NADP from ¹⁴C-carbonyl-nicotinic acid was essentially the same as that reported for animal tissues and micro-organisms. The permanent bleaching of *Euglena gracilis* by nitrofurans derivatives was discussed by D. R. McCalla (McMaster, Hamilton). Other mutagens and radio-mimetic agents were used as bleaching agents, but only *N*-methyl-*N*-nitroso guanidine proved non-lethal. It was suggested that these bleaching agents damaged chloroplast DNA. Continued interest in the biosynthesis of aromatic compounds and phenolase enzyme systems was reported by A. C. Neish *et al.* from the Atlantic Regional Laboratory (N.R.C., Halifax). In particular the biosynthesis of the cinnamic acid derivatives as the C₆-C₃ intermediates in lignin formation was discussed. Other biochemical contributions of interest dealt with the *in vitro* synthesis of glycine and the metabolic utilization of ¹⁴C-ethanol (E. A. Cossins *et al.*, Alberta). N. E. Good (Michigan) discussed the preparation of several new H ion buffer systems. They were mostly substituted derivatives of *tris*(hydroxymethyl)-amino methane covering the pH range from 6 to 8 and were claimed to be superior to both *tris* and phosphate buffers.

Several contributions described studies of the structure and the effects of environment on plant cells by electron microscope and light microscope. A. J. Mia and G. Setterfield (Carleton, Ottawa) reported the synthesis of cell wall material by apposition in *Rauwolfia* sclereids using ³H-glucose pulse labelling. In a session on translocation in the higher plants, contributions from the Biosciences Division (N.R.C., Ottawa) described the experimental

control of ^{14}C -sugar movement by changing the node temperature (J. A. Webb and P. R. Gorham), and discussed the distinct lack of evidence demonstrating sugar conduction in the sieve tubes (D. C. Mortimer and M. Suzuki). D. S. Fensom and D. C. Spanner (London, England) reported their measurements of microelectrode potentials in the conducting tissue of *Nymphoides* and *Heracleum* and calculated that the electro-osmotic efficiency was sufficient to maintain sugar flow through partially blocked sieve plate pores.

In a final session on plant growth substances, several contributions were concerned with the influence of exogenously supplied gibberellins and IAA on plant development. Three reports discussed the interesting problems of IAA conjugation in plant tissues. E. Schneider and F. Wightman (Carleton, Ottawa) showed IAA-2- ^{14}C to be metabolized mainly through conjugation to indoleacetyl aspartic acid, indoleacetyl glucose and 2-OH indoleacetylglucose in barley seedlings over a 24-h period. A. Winter and K. V. Thimann (Harvard University), however, could find no evidence for conjugate compounds over a 2-h period in *Avena* coleoptiles and con-

sidered fed ^{14}C -IAA to be physically bound to a protein fraction. N. A. Andreae (Department of Agriculture London) showed that conjugate products were formed with IAA inactivation, when pea roots were pretreated with an excess of IAA and NAA. An adaptive period of 2-4 h was necessary before the conjugate products were discerned. 2,4-D was not conjugated and remained inhibitory regardless of the pretreatment time. J. I. Toohey and C. D. Nelson (Queens, Kingston) reported two new herbicides derived from a soil bacterium inhabiting old pastures. The compounds were toxic to algae and higher plants but not to insects, fish or mammals. They were isolated and identified as phenazine-1-carboxylic acid (most toxic to higher plants) and the 2-OH derivative (most toxic to the algae).

Officers of the society elected for 1965-66 were: *President*, Dr. G. H. N. Towers (University of British Columbia); *Vice-president*, Dr. D. Simminovitch (Department of Agriculture, Ottawa); *Secretary-treasurer*, Dr. D. Canvin (Queens, Kingston); *Eastern director*, Dr. A. R. A. Taylor (University of New Brunswick); *Western director*, Dr. M. S. Spencer (University of Alberta). J. A. WEBB

A REGISTER OF SCIENTIFIC RESEARCH IN THE NETHERLANDS

IN 1964 the Netherlands Organization for the Advancement of Pure Research (Z.W.O.) began a register of scientific research in the Netherlands. The results of this work are to be published in the form of a periodical guide giving details of current scientific investigations. The purpose of this guide is to foster contact between research scientists. It supplies both Dutch and foreign scientists with information on the research being carried out in the Netherlands. With the view of foreign readership it appears in English.

For recent scientific information the research scientist must depend either on personal contacts or on articles in journals, reports, etc. In the case of leading scientists such as university professors working in small and highly specialized fields, personal contact often provides sufficient communication; however, this is much less true of their staff. As regards research scientists in larger and above all multi-disciplinary fields, personal contact usually satisfies only a small part of the need for communication.

So far as journals, reports, etc., are concerned, not only does it take a long time until the original publications are reported in abstracting journals, but also there is a considerable interval before the results of a research project are published. Moreover, the research scientists concerned may have information available long before then. It may also be remarked that a great deal of research is never published, for a variety of reasons, for example in the event of discontinuance of the project; valuable information may be lost in this way.

The marked expansion of research at the universities makes it still more desirable that the need for recent scientific information be satisfied. The guide contributes towards this by presenting research scientists with a basis on which further contacts can be established.

The guide has been inspired by the British publication *Scientific Research in British Universities and Colleges*, published by the Department of Scientific and Industrial Research and the British Council; this gives concise information on scientific research in Great Britain*.

At first there was some doubt about the value of this publication in Britain, but in the course of the years its utility has been clearly proved. Consequently, Z.W.O. decided to build up experience by starting in one field and

submitting the result to scientists for discussion; physics was chosen as this first field.

In principle the guide only mentions research projects by or under the direct control of professors, lecturers and scientific staff.

Taking into account the purpose of the guide, preference was given to a main grouping by subject rather than by university department. As research scientists are best served by a classification that they already know, it was decided to follow the leading abstracting journal for each field of science. As the register is extended to more fields the disadvantage will have to be accepted of a certain lack of balance as compared with a general classification, such as the Universal Decimal Classification, which was devised as a whole.

For physics, *Physics Abstracts*, published by the Institution of Electrical Engineers, London, has been chosen. The research scientist was asked to classify his research project under one of the eighteen headings of *Physics Abstracts*. In order to reduce discrepancies to a minimum, a copy of the classification followed by this journal was attached to the questionnaire.

In the guide the research projects are arranged under the afore-mentioned headings of *Physics Abstracts*. Within these groups there is a sub-division according to the institution where the research is being carried out. Besides a name index and a subject index, a list of co-operating research institutes, with their addresses, is given.

Before questionnaires were sent out, the arrangement was submitted to the chairmen of the physics departments of the various universities. The idea of this was to obtain their criticism in good time, so that allowance could be made for it in the questionnaire; most of them also proved ready to call on the co-operation of the professors and lecturers to be covered by the survey.

The questionnaire was kept simple so that filling it in would not take up too much of the scientist's time. Only those questions were asked which are directly connected with the three questions which the guide tries to answer, namely: (1) What kind of research is being done? (2) Who is doing it? (3) Where is it being done?

To every professor and lecturer of physics were sent 5-10 questionnaires on which to report the relevant research; in most cases they were sent direct, though in

* Now published by the Department of Education and Science and the British Council (*Nature*, 207, 691; 1965).

a few cases they went to a contact person for distribution to all the research scientists at a certain institution.

Although for practical reasons the first survey had to be confined to the universities, a small number of other bodies doing important physical research were also included in this first trial. Owing to the fact that investigations in borderline fields, such as physical chemistry and biophysics, are likewise done in non-physical laboratories, complete coverage was not entirely possible even within the universities; it will, however, be approached as the registration progresses.

For rapid processing of the data received—particularly with the view of future expansion to more fields—mechanization is desirable. In the case of the first guide the procedure was as follows: The copy is typed in the order in which it is received on a 'Flexowriter' which produces a punched tape as well as a typescript. After the copy has been completed the punched tape is read by a computer. This arranges the data for text and indexes in the desired order and records these on a new punched tape. The latter is then run through a 'Flexowriter'

which types the manuscript for the printer without manual intervention. The pages are made up and reproduced in photo-offset.

In the preparation of the guide, Z.W.O. has received the assistance of the Statistics Department TNO for the mechanical processing of the copy and of the State Printing Department for printing. The title of the first publication, which has just appeared, is *Current Research in the Netherlands, Physics, 1965* (Pp. 66. The Hague: Netherlands Organization for the Advancement of Pure Research (Z.W.O.), 1965). The guide for physics covers about 500 current research projects on which about 750 scientists are engaged. Institutions and research scientists can obtain this publication free of charge from the Dutch Embassy in their country, or direct from the Netherlands Organization for the Advancement of Pure Research (Z.W.O.), P.O. Box 2138, The Hague.

For the following issue of the register the choice has fallen on biology; this will be registered in co-operation with the Royal Netherlands Academy of Sciences. Other sciences will follow.

S. T. GROENMAN

OBSERVATIONS OF A STRONG UNIDENTIFIED MICROWAVE LINE AND OF EMISSION FROM THE OH MOLECULE

By PROF. HAROLD WEAVER, DR. DAVID R. W. WILLIAMS, DR. N. H. DIETER and W. T. LUM

Radio Astronomy Laboratory, University of California, Berkeley

AN investigation of the galactic distribution of the OH molecule as shown by the microwave lines arising from transitions between the hyperfine levels of the ground state has led us to the following general conclusions: (1) The OH molecule is sharply confined to the galactic plane. In the plane, however, we detect OH in absorption in virtually every source brighter than a specifiable limit. (2) The OH molecule is in emission in some sources. (3) A strong unidentified emission line is present at frequency 1,665 Mc/s in a number of sources.

This discussion deals with the last two of these topics. We shall consider the galactic distribution of OH elsewhere.

Our observations were made with the 85-ft. antenna and the 100-channel switched-frequency double-comparison receiver and digital data system recently installed at the Hat Creek Radio Observatory. This system, which will be described elsewhere in detail by one of us¹, provides a spectrum consisting of 100 contiguous spectral elements which are either 10 kc/s or 2 kc/s wide. The band-width of the spectral elements is fixed by interchangeable crystal filters. The receiver includes a tunable parametric amplifier having a band-width of about 20 Mc/s. The total system noise temperature (including instrumental effects such as spill-over and the like) is approximately 130° K.

An 'observation', as the term will be used in this discussion, consists of the difference between the spectrum as observed for a specified source (integration time 1,600 sec) and the spectrum of a comparison region (integration time 1,600 sec) near the source but sufficiently far away so that the source is out of the antenna beam.

Observations of a strong unidentified microwave emission line. The Orion Nebula has been thoroughly searched for OH at 1,667 Mc/s by Robinson, Gardner, van Damme and Bolton². They found no line and set an upper limit of 0.005 to the optical depth of OH in the direction of Orion. We concur with Robinson *et al.* that there is no observable line at 1,667 Mc/s. However, our observations of Ori A at 1,665 Mc/s show several emission components

with a maximum antenna temperature of 3° K when the spectral resolution is 10 kc/s (Fig. 1).

W3, a bright extended H II region which we have also observed, shows, at 1,367 Mc/s, an absorption component of OH with a depth of approximately 1° K (Fig. 1). At 1,665 Mc/s we find, as would be predictable, the second strongest OH microwave line arising from the ground state. The depth of the 1,665 line, again as predicted, is about 0.5° K. At 1,612 Mc/s there is no absorption feature visible (Fig. 1) in the one observation we were able to make before this investigation ended. Our single observation is inadequate to show the expected OH feature at 1,612 Mc/s (predicted depth ~0.1° K), but it is adequate to demonstrate that there are no large anomalies at 1,612 Mc/s. The outstanding feature of these three spectral regions is the intense emission feature (maximum antenna temperature 8.2° K for 10-kc/s spectral resolution)

Fig. 1. Spectra of Ori A and W3 with a resolution of 10 kc/s (1.8 km/sec). Frequency and velocity scales are with respect to the local standard of rest. The frequencies in the 1,667 Mc/s spectrum of W3 should be decreased by 0.10 Mc/s. Those in Ori A should read 1,665.80, .60, .40, .20, .00. The ordinate is antenna temperature

upward in frequency from the 1,665 line of OH. In Fig. 2 we exhibit this strong emission line in *W3* (and the OH absorption feature downward in frequency from it) with spectral resolution 2 kc/s. With this high spectral resolution we observe a maximum antenna temperature of 31° K.

There is no known identification of the strong emission line at 1,665 Mc/s shown in Fig. 1. In what follows, for brevity in writing and to emphasize the surprising nature of the observation just presented, we shall speak of this unidentified line as arising from 'mysterium'.

We have observed 'mysterium' in two other thermal radio sources also: *W51* and *W75*. In each of these we find OH weakly in absorption and of normal intensity ratio for the lines at frequencies 1,667/1,665 Mc/s. Additionally, for each of the sources *W51* and *W75* we find a weak emission feature at 1,665 Mc/s that has no counterpart at 1,667 Mc/s. In general, in behaviour, these sources resemble the more extreme case *W3*.

Observations of OH in emission. In two sources, *W49* and *NGC 6334*, we find OH in emission. Spectra of these objects at 1,667 Mc/s and 1,665 Mc/s, spectral resolution 2 kc/s, are illustrated in Fig. 3.

W49, reported as a point source by Westerhout³, is a heavily obscured H II region recently investigated by Akabane and Kerr⁴. On the basis of their hydrogen absorption observations they point out that *W49* is at a probable distance of 15 kpc, and that its intrinsic energy output at 1,420 Mc/s is 300 times as great as that of the Orion Nebula and one-fourth as great as that of 30 Doradus.

NGC 6334 has been less well investigated than *W49*. The *NGC* object is one of a compact group of emission nebulae which are probably optically visible parts of one object which is crossed by dense variable obscuration. Photographs of *NGC 6334* have been published by Duncan⁵. Clark, Radhakrishnan, and Wilson⁶ report a hydrogen absorption feature at +27 km/sec and infer a distance to *NGC 6334* > 0.8 kpc. It thus appears that in the 1 Gc/s range the intrinsic energy output of *NGC 6334* is greater than that of Orion but less than that of *W49*.

The spectra of *W49* and *NGC 6334* are complex, consisting of numerous narrow emission maxima, some of these (as exemplified in the 1,667 line illustrated in Fig. 3) being as sharp as 5 kc/s (1 km/sec) at half-intensity. In the spectrum of *NGC 6334* there is present OH absorption as well as OH emission.

These spectra are unusual not only because they show OH emission; they are also unusual because the intensity

Fig. 2. Spectrum of *W3* at 1,665 Mc/s with a resolution of 2 kc/s (0.4 km/sec)

The narrowness of the features is the more surprising because the emission appears to be associated with the central regions of bright diffuse nebulae, where mass motions are typically 5 or more km/s, and temperatures are 10^4 °K. We do not know the atomic or molecular weight of 'mysterium'. We can, however, assume various weights, attribute the entire width (0.4 km/sec) to thermal broadening and compute an upper limit to the kinetic temperature of 'mysterium'. If the weight of 'mysterium' is equal to the atomic weight of He, $T_{kin} \leq 14^\circ$ K; if it is equal to OH, $T_{kin} \leq 50^\circ$ K; if it is equal to Ca, $T_{kin} \leq 140^\circ$ K. The kinetic temperature of 'mysterium' must be very low; turbulence must be negligible.

The extraordinary sharpness of the 'mysterium' features indicates that the transition probability for the 1,665 'mysterium' transition must be quite low and that the principal energy-level involved must either be the ground state or have a long half-life.

Indications are that the rest frequency of the 'mysterium' line is higher than the 1,665.402 Mc/s line of OH.

In those sources in which the two lines can be conveniently compared, the 'mysterium' line appears at a slightly higher frequency than the 1,665 Mc/s of OH in the same source.

We thank Mr. David Lesh and the staff at the Hat Creek Observatory for their assistance in making the observations and Mr. A. F. Setteducati for his help in making the reductions.

The 100-channel receiver was constructed with the aid of a grant from the U.S. National Science Foundation. The Hat Creek Observatory is operated under contract Nonr 222(66) with the U.S. Office of Naval Research.

PRESSURE DISTRIBUTION IN THE TETRAHEDRAL ANVIL APPARATUS

By J. LEES

Standard Telecommunication Laboratories, Ltd., Harlow, Essex

PRESSURES above 20 kbars cause most conventional fluids to solidify at room temperature, so that apparatus for generating pressures in this range relies mainly on solid pressure transmitting media. The use of pyrophyllite, a natural aluminium silicate, is widespread, particularly in apparatus of the 'belt' or 'anvil' types^{1,2} where its high shear strength at pressure allows the formation of pressure-retaining gaskets (see, for example, Bundy, ref. 3). At the same time, its low compressibility allows pressure generation within the test cell. Since the shear strength is high, the stress system within the test cell at pressure would be expected to be neither hydrostatic nor uniform, and this is especially the case in anvil apparatus where relatively large movements of material occur during gasket formation⁴. Such variations in stress could be large, and so introduce uncertainties in pressure measurement in physical and chemical experiments at ultra-high pressure.

Stress inhomogeneities have been demonstrated in both anvil and cylindrical ultra-high-pressure apparatus, by observation of the 'smearing out' effect^{5,6} produced on the normally rapid I→II resistance transition in bismuth at 25.4 kbars (ref. 7). To minimize this effect, pressure calibration specimens are usually surrounded by a 'pressure equalizing' sleeve made from a low shear strength material, typically silver chloride. Pressure within such a sleeve is expected to be reasonably hydrostatic and closely related to the mean hydrostatic stress in the surrounding pyrophyllite. By using sleeved calibration specimens at various positions within the cell (following the work of Deaton and Graf⁸), the variation of this stress has been determined for an N.B.S.-type tetrahedral apparatus⁹, at pressures around the 25.4-kbar bismuth transition.

The apparatus used had steel anvils of 3.81 cm edge, to En26 specification, with a hardness of 530 d.p.n.; these were coated with jeweller's rouge prior to each experiment. Pyrophyllite for the tetrahedra was obtained under the trade name of 'Alsil': we have found this particular grade to be of excellent quality, machining easily, and quite free of the foreign inclusions sometimes encountered. The calibration samples in these experiments consisted of bismuth wires 1 mm diameter × 5 mm long. These were mounted in silver chloride sleeves of 3 mm outside diameter. Electrical contact was made

directly to the anvil faces by suitably shaped soft copper plugs; by using all four anvils, the resistance of three samples could be followed simultaneously as the anvil load was increased.

Two sets of experiments were performed. In the first, the samples were located as in Fig. 1a: No. 1 was at the centroid; No. 2 with its centre on the line joining the centroid to a mid-point (half-way along an altitude) of a face; No. 3 on the normal from the centroid to an edge.

Fig. 1. Sample positions in tetrahedron. a, No. 1, at centroid; No. 2, between centroid and mid-point of face; No. 3, between centroid and edge. b, No. 4, at face centroid; No. 5, at mid-point of altitude; No. 6, towards apex (see text). The arrangement of Nos. 5 and 6 corresponds to deformed tetrahedron.

Distances from the centres of samples No. 1 to No. 2 and No. 1 to No. 3 were 6 mm and 7 mm respectively. Fig. 2 shows the loads at which the 25.4 kbar transition was observed to begin at each of the sample positions, and for various degrees of tetrahedron oversize. (The variables P and V are, respectively, the transition load divided by the load necessary to produce the transition pressure over an area equal to an anvil end-face, and the precompression tetrahedron volume divided by the tetrahedron volume defined by the anvil end faces.) Maximum variation in load in repeated experiments is estimated at ± 4 per cent: I believe that this is mainly due to small differences in the mechanical properties of pyrophyllite in a given batch of tetrahedra.

It will be seen that the differing values of P in Fig. 2 imply quite appreciable pressure gradients in all cases; also that the optimum value of V (based on the minimum load to reach the transition) is much the same for all three specimen positions. Values of P and V at the minimum for sample 1 are 1.00 and 1.95, agreeing well with the corresponding results of Houck and Hutton⁶ for $\frac{1}{2}$ -in. and 1-in. tetrahedral units with carbide anvils.

In the second set of three experiments 4.76-cm tetrahedra ($V=1.95$) were used. Samples were arranged on an altitude of a face as shown in Fig. 1b. Sample No. 4 was at the face centroid, No. 5 half-way along the altitude from the vertex to the base, and No. 6 towards the vertex the same distance from No. 5 as the latter was from No. 4, that is ~ 5.5 mm. Reasonably consistent transition loads on increasing pressure were found for samples Nos. 4 and 5, typical values of P being 1.07 and 1.13 respectively. Values of P for No. 6, however, varied considerably, two samples giving 1.27 and 1.36 respectively; the third had not transformed at $P=1.4$ which was the maximum load applied in these experiments.

If the two sets of experiments on 4.76-cm tetrahedra are now combined, a rough picture emerges of pressure falling off fairly slowly from the centroid towards the faces, and rather more rapidly towards the edges. It is difficult to relate the values of P at each sample to corresponding pressures at each of the other samples, since we do not have a load/pressure relation for each sample position. However, an approximate relation may be derived by assuming it is of the same general shape normally observed¹⁰, and differs only by a proportional factor in load (determined by the value of P) at each sample position. This assumption is probably not very greatly in error since the actual pressure range involved around 25.4 kbars is small. Pressures derived on this basis when sample 6 is at 25.4 kbars (the minimum observed value of P of 1.27 is used) are shown in Fig. 3 displayed with a cross-section of the deformed tetrahedron. It should be noted that the actual physical displacement of the

Fig. 2. Loads to produce B.I.U. 25.4-kbar resistance transition at three sample positions for various tetrahedron sizes. \circ , Sample No. 1; Δ , sample No. 2; \square , sample No. 3.

Fig. 3. Sample positions on a mid-section of the deformed tetrahedron, with corresponding pressures on loading (figures in parentheses for sample Nos. 1 and 6 are for unloading).

Fig. 4. Tetrahedron after compression, showing dark area on face

samples due to compression of the tetrahedron was found to be small, except in the case of sample No. 6 as shown. This would be expected if, as seems very reasonable, the flow pattern of pyrophyllite during compression is similar to that previously derived for a 1.90-cm edge tetrahedral apparatus⁴.

The reverse transition loads on unloading were also determined, and with the exception of sample No. 1, were found to be somewhat unrepeatable. Generally, however, pressure gradients were greater during unloading. Thus, for sample No. 6, the minimum value of P for the II \rightarrow I transition obtained was 1.10, compared with 0.72 for sample No. 1; the corresponding pressures are shown in Fig. 3 in parenthesis. It will be noted that, on loading, the pressure difference between No. 1 and No. 6 corre-

sponds to 14 per cent of the pressure at No. 1; on unloading the minimum difference is increased to 24 per cent.

Fig. 3 shows that in the experiments with 4.76-cm tetrahedra (a) there is a small but definite pressure gradient in the central regions with a larger gradient towards the edges and apices, and (b) gradients appear to be increased on unloading. Maximum pressure is generated at the tetrahedron centroid, thus confirming the suspected intensification effect noted by Houck and Hutton⁶; a similar effect has been observed in a cylindrical high-pressure apparatus by Tydings and Giardini⁵. Both groups of research workers ascribed the effect to possible 'cones' of undeformed pyrophyllite which act as anvil (or piston) extensions of small area, so increasing pressure in the central regions. Further evidence for 'cones' of pyrophyllite is provided by flow patterns in deformed tetrahedra⁴, and by the appearance of tetrahedron after compression. The dark marks (Fig. 4) on each face are due to material which has not sheared during compression: these marks very probably represent the bases of such cones. Actual pressure differences inferred for the central regions of the tetrahedron are ~7 per cent between centroid and face. These would account for the changes previously observed in the load/pressure relation when different lengths of calibration sample are used⁴.

The present results thus show gradients considerably greater in the central regions than the 1 per cent found by Deaton and Graf in their experiments at various pressures with a 1.98-cm edge tetrahedral apparatus.

This could be associated with the relatively smaller pressure-sensing samples in the experiments described here (the dotted line in Fig. 3 shows Deaton and Graf's sample size on the same scale), but it could also be due to the differing absolute tetrahedron size or even to the use of steel anvils. Another possibility lies in variations in the properties of pyrophyllite: small differences which are found in the grain of machined surfaces, and in the machining properties, could well point to such an effect. Generally the pressure variations observed in the particular experiments described here indicate the need for caution in pressure calibration work, even when a pressure calibrating sample is included with the specimen under investigation: this is particularly so when the calibration sample is situated some distance away from the specimen.

I thank my colleagues K. Ashcroft and C. H. L. Goodman for discussions; also D. G. Ingham, who carried out many of the experiments.

ELECTRIC POTENTIALS GENERATED BY FREEZING DILUTE AQUEOUS SOLUTIONS

By H. C. PARREIRA* and A. J. EYDT

Stanley-Thompson Laboratories, School of Engineering and Applied Science, Columbia University, New York

THE purpose of this article is to describe an investigation of the large electric potentials which occur when very dilute solutions freeze under the influence of a temperature gradient. This phenomenon is identical to the thermoelectric effect discovered by Costa Ribeiro¹. Since the discovery of electrical potentials associated with freezing of aqueous solutions of inorganic compounds was first announced, little systematic investigation has been reported².

When water is frozen under the influence of a temperature gradient, if certain precautions are taken, a potential can be measured between the ice and the water phases. It was established by the work of previous investigators²⁻⁴ that the freezing potential does not depend on the temperature of freezing alone; it depends on the rate of freezing and also on the concentration of the impurities present in the system. Most of the work published on the influence of electrolytes on freezing potentials of aqueous solutions deals with concentrations above 10^{-5} M. The few data available for solutions below that concentration show practically no electrical effects.

It was found in the course of the present work that the concentration range between 10^{-7} and 10^{-5} M presents potential values which are even larger (but of opposite sign) than those reported for concentrations above 10^{-5} M. These findings are at variance with previous works published on the influence of electrolytes⁵. The treatment of the conductivity water is probably one of the causes of this disagreement.

The phenomenon set up by the temperature gradient imposed on the system is easy to reproduce if the many parameters involved are carefully controlled. Devices

used in earlier work³ for that specific purpose probably failed to control accurately the experimental parameters on which the electrical phenomena are dependent, thus the failure to reproduce the potentials.

The results reported here were obtained with an apparatus which ensured good temperature control. The main part of the apparatus is composed of a freezing cell which consists essentially of a cup (about 1 cm³) made of a 'Teflon' sleeve that fits snugly in a brass cylinder. The top of the brass cylinder (the bottom of the freezing cell cavity) is covered with a gold plate to prevent direct contact between the brass cylinder and the solution. The cell is depicted in Fig. 1. An alumel-'Chromel' thermocouple is placed just under the gold plate, ensuring accurate temperature measurements. The cell is next placed in a cylindrical copper well (diam. 1.6 cm, depth 2 cm). The copper well is part of a thermoelectric heat pump and can be cooled down to -30° C with the loaded cell in place; the cooling unit is represented in Fig. 2. The temperature in the well (and cell) is dependent on the current flowing through the thermoelectric modulus, and the power unit supplying the modulus current is fitted with a current read out. The temperature at the bottom of the copper well is also determined with the help of a thermocouple attached to the bottom of the well; the power unit read out is then used for temperature control. The freezing potentials were measured with the help of a Keithley electrometer model (610 amp) the output of which was fed into a Varian recorder. A potential divider built with precision resistors had to be made because the potentials often exceeded the useful range of the electrometer.

A platinum wire immersed in the water phase was connected to the electrometer; the ice phase was grounded

* Present address: Central Research Laboratories, Interchemical Corporation, Clifton, New Jersey, U.S.A.

Fig. 1. Freezing cell

Fig. 2. Freezing well

through the bottom of the cell (Fig. 1). In this article the maximum potential values are given, that is, the highest potential value attained in the potential versus time curve. The time of occurrence of the maximum potential seems to depend on concentration, the other parameters being kept constant. For example, for 2×10^{-4} M solution of ammonium chloride the maximum potential value was observed to occur 2 min after the beginning of the experiment, whereas pure water developed the maximum value nearly 10 min after the solution was placed in the cell. The time corresponding to the maximum potential appears to increase with the decreasing concentration of ammonium chloride; no trend was observed, however, for other electrolytes such as hydrochloric acid and sodium chloride. In all cases the freezing potential value drops practically to zero at the moment of complete solidification of the water phase. In the device used in the study described here complete freezing occurs between 14 and 16 min after starting the experiment. The results reported here were obtained under the following experimental conditions: Room temperature, $24 \pm 1^\circ \text{C}$; brass cylinder, $-25 \pm 1^\circ \text{C}$; initial volume of liquid phase, 0.8 cm^3 ; height of cell, 1.5 cm ; cross-section, 0.64 cm^2 . The solution was pipetted into the cell once the temperature of the brass cylinder reached -25°C . The platinum electrode was lowered into the water phase. The potential, which appeared immediately after the solution was placed in the cup, was then measured. The

details of the construction of the whole experimental apparatus were given elsewhere⁶.

The effect of temperature on the freezing potentials of water and dilute aqueous solutions of electrolytes was examined earlier³.

The effect of the addition of both organic and inorganic substances has been investigated and is briefly reported here. No effort was made to eliminate carbon dioxide, although fresh solutions were made up with recently distilled water. Bidistilled water from an all-Pyrex[®] water still was used (conductivity $1.2 \times 10^{-6} \text{ mho cm}^{-1}$). This water gave freezing potentials of $+75 \text{ V}$ (mean of 18 independent determinations). The freezing potential dropped to $+40 \text{ V}$ for once-distilled water (conductivity $1.8 \times 10^{-6} \text{ mho cm}^{-1}$) and decreased to zero for distilled water of conductivity around $4 \times 10^{-6} \text{ mho cm}^{-1}$. Generally no relationship could be found between the water conductivity and the freezing potential; however, the E_m versus conductivity plot for sodium chloride gave an excellent straight line up to 10^{-5} M (conductivity range: 1×10^{-6} – $3 \times 10^{-6} \text{ mho cm}^{-1}$). The E_m for dilute solutions was plotted against the logarithm for the molar concentration. Very dilute solutions of organic and inorganic substances showed a similar behaviour except solutions containing the NH_4^+ ion. The freezing potential for aqueous solutions drops to zero in the concentration range between 10^{-7} and 10^{-5} M . The potential often reverses its sign, in the case of many inorganic salt solutions, beyond $c \approx 10^{-5} \text{ M}$ and drops to zero at a concentration around 10^{-3} M ; however, the magnitude of the maximum potential is much smaller than that observed for the potentials measured in the dilute region (10^{-7} – 10^{-5} M). The freezing potential of solutions of inorganic acids drops to zero at $c = 10^{-3} \text{ M}$ and remains at zero beyond that concentration value. All organic substances investigated (sucrose, glucose, urea, etc.) also cause a drop in the potential, which is eliminated altogether at concentrations around 10^{-3} M ; however, the potential sign is never reversed. The E_m versus $\log c$ plots for ammonium chloride and sodium chloride are presented in Fig. 3. Two regions can be observed in the sodium chloride curve: (a) a very dilute region I showing large potentials and a positive ice phase; (b) a region II where the ice is negatively charged with respect to the water phase but never shows the large potential differences which occur in region I. Between the two regions there is a narrow concentration range where the potential shows an erratic behaviour and very low values. The behaviour of ammonium chloride is quite different, as is shown in Fig. 3. A maximum is found at $c = 2.5 \times 10^{-6} \text{ M}$ for which $E_m = +115 \text{ V}$; the potential, however, drops to zero at $c \sim 10^{-3} \text{ M}$. The chlorides of Ca^{++} , Ba^{++} , Sr^{++} and Mg^{++} also reverse the sign of the freezing potential,

Fig. 3. Influence of electrolytes on freezing potential of water, E_m versus $\log c$; block temperature -25°C . \circ , NaCl; \times , NH_4Cl

Fig. 4. Influence of aliphatic alcohols on freezing potentials of water E_m versus $\log c$; block temperature -25°C . \times , Methanol; \bullet , ethanol, \circ , propanol; $+$, butanol; Δ , pentanol; \square , hexanol

but do not show potential values as high as those produced by metallic uni-univalent electrolytes. The chlorides of Fe^{+++} , Al^{+++} and Cr^{+++} show only a region I; beyond 2×10^{-6} M the freezing potential is zero. The 'charge reversal' appears to be a property of uni-univalent and uni-divalent metallic salts, with the exception of those containing the NH_4^+ ion.

The large freezing potentials obtained for conductivity water are in agreement with the findings of Workman and Reynolds³ but are at variance with the results obtained by Lodge *et al.*⁵, who could not measure any potential for conductivity water passed through an ionic exchange resin column. The influence of a series of organic compounds such as sugars, glycols, alcohols, ketones and urea has also been investigated. The behaviour of aliphatic alcohols from methanol to hexanol is remarkably similar, as is shown in Fig. 4.

A theoretical interpretation of the electrical phenomena which appear during the course of a phase transition is not easy^{1,8}. If all macroscopic parameters (temperature gradient, rate of freezing, orientation of the crystallographic axis of the ice formed) are kept invariant, then it is possible to ascribe the phenomenon to the following processes: (1) proton conductance; (2) dipole orientation of water molecules at the ice/water interface; (3) ionic entrapment in the ice lattice; (4) ionic diffusion.

The proton conduction process, whether taking place by quantum mechanical tunnel effect, rotation of water molecules or any other rate-determining mechanism, could be the predominant factor in the production of the freezing current, although process IV may be at play when ionic impurities are present (Fig. 3). In fact the tunnel effect has been suggested (from theoretical considerations) by others as a possible rate-determining mechanism for the proton gumping process^{9,10}.

Mechanism (2) may be largely responsible for the existence of the high potential values between the ice and the water phases in region I, although mechanism (1) may be operating throughout the whole concentration range investigated. Furthermore, because it is impossible to rule out completely the presence of ionic entrapment in the ice lattice, it is also possible that mechanisms (3) and (4) are also at play even at very low ionic concentrations (region I); their contribution, however, would be small in region I. The process of ionic entrapment alone does not seem to explain clearly the presence of a freezing current, as it does not explain the large potentials in conductivity water. It is possible that all processes are at play in region II, although dipole contribution would be smaller than the others. In region I the proton conduction mechanism may originate the freezing current, whereas the dipole orientation contribution at the ice/water interface may build up the large freezing potentials.

The following results were obtained for a 6.25×10^{-6} M ammonium chloride solution: $E_m = +110$ V (maximum

potential, ice positive), $i_m = 1.0 \times 10^{-9}$ amp (maximum current) and $q = 5.7 \times 10^{-7}$ coulombs (1,700 e.s.u. c.g.s., total charge transferred per gram of water). The value given here for the charge is the maximum value obtained in the concentration range between 10^{-6} and 2×10^{-3} M. The values obtained by other investigators³ (for the same substance and same concentration range) exceed by orders of magnitude the values reported here, a fact which could not be explained at the time. The use of dipole orientation to explain the appearance of the phase transition potentials is in agreement with the findings of Costa Ribeiro¹, who suggested that the ice/water interface is the site of the electrical phenomena reported here. This view was also the basis of the theoretical treatment of B. Gross⁸, confirmed experimentally by Gill and Alfrey¹¹, Cobb¹² and by ourselves⁷. Moreover, because of chemical bond requirements between the molecules at the interface and those present in the liquid bulk phase, it is to be expected that the preferential dipole orientation of the water molecules may extend to a considerable depth. This interfacial region is thick enough to accommodate a number of layers of water dipoles. The dipole orientation occurs at both the air/water and the ice/water interface. However, the contribution of the dipoles at the air/water interface is much smaller than that of the several dipole layers at the ice/water interface because of the more random nature of the air/water interface. No surface orientation is likely to occur inside the ice phase as a consequence of the loss in configurational entropy of the ice lattice. Experiments carried out in these laboratories indicate that the dipole orientation contributions at both interfaces are being determined while the measurements of freezing potentials are made. Assuming that the surface phase (in the water) near the ice can accommodate a few layers of oriented dipoles (say, 5 layers) and that there are $c. 10^{15}$ dipoles per sq. cm, a value of 22 V is calculated; an array of 15–20 dipole layers would account completely for the large potential values obtained for conductivity water. Fletcher¹³, using a thermodynamic approach and elementary electrostatics, found a value of 30 V for the potential in the ice. In conclusion it seems possible that the electric potentials caused by the freezing of conductivity water and very dilute solutions are largely due to orientation of water dipoles at the ice/water interface. The predominant processes occurring in region II could be, in the decreasing order of importance: proton conduction, ionic entrapment and ionic diffusion. In region II the dipole orientation contribution would be small. The elimination of the freezing potential by organic molecules could be explained, at least qualitatively, if one accepts the presence of the proton conductance mechanism and the surface orientation of the water dipoles. The organic molecules behave as a proton trap¹⁴, thereby eliminating the freezing current, and also as a disorganizing agent of the dipole arrays at the interface causing the complete annihilation of the freezing potential.

RELATIONSHIP OF THE VELOCITY OF A CHARGED PARTICLE TO ITS RELATIVE BIOLOGICAL EFFECTIVENESS

By DR. J. E. TURNER

Health Physics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee

AND

HAL HOLLISTER

Division of Biology and Medicine, U.S. Atomic Energy Commission, Washington, D.C.

THE relative biological effectiveness (RBE) of an incident charged particle is often discussed in terms of its rate of linear energy transfer (LET). When most of the energy transferred is absorbed locally in a small target (for example, a single cell), RBE is described as a function of LET_∞ , which is the stopping power $-dE/dx$ of the target for the particles¹. Because stopping power depends only on the two properties, charge and velocity, of the incident radiation², RBE thus described for a particle is a function of its charge and velocity. In what follows, the 'LET dependence' of RBE will imply a dependence on both these quantities. We shall restrict the discussion to small targets in which the spatial dose distribution is uniform.

The ratio of RBE values of two radiations, RBE_1 and RBE_2 , is given in terms of absorbed doses, D_1 and D_2 (energy absorbed per unit mass), by the relation:

$$\frac{RBE_1}{RBE_2} = \frac{D_2}{D_1} \quad (1)$$

In comparing the two radiations, the absorbed doses are adjusted experimentally to produce the same degree of biological effect, or end-point; other factors in the experiment, such as dose rate and species, are held constant. When a mono-energetic beam of charged particles passes normally through the face of a thin slice of tissue, the absorbed dose in the tissue can be expressed by writing $D = \phi(-dE/dx)\Delta x/100\Delta m$. Here ϕ denotes the flux of particles in cm^{-2} , $-dE/dx$ is the stopping power of tissue for the radiation in ergs/cm, Δx is the thickness of the tissue slice in cm and Δm its mass in grams, and the factor 100 converts ergs/gram into rads (1 rad = 100 ergs/g). The ratio of RBE values of two kinds of charged particles, therefore, is given by:

$$\frac{RBE_1}{RBE_2} = \frac{\phi_2}{\phi_1} \cdot \frac{(dE/dx)_2}{(dE/dx)_1} \quad (2)$$

In recent years a number of investigations have extended and generalized dosimetric concepts to cover a wider range of phenomena than before³. One group of investigations has led to a quantitative description of RBE in terms of the physical properties of radiation for certain biological end-points⁴. This theory, which appears to describe the RBE of neutrons, photons, electrons and singly charged ions, and to give reasonable results for α -particles, implies that RBE depends only on the velocity of a charged particle rather than LET⁵. The theory thus implies that the RBE of a charged particle is independent of the particle's charge. This finding differs from the conventional description of RBE¹.

The present article attempts to clarify the question of charge dependence of RBE by the application of general principles of collision theory. Although the interactions and mechanisms that lead from an initial physical event between radiation and matter to biological damage are doubtlessly complex, the way in which charge enters the picture is given explicitly in the formalism of quantum mechanics. (The same is also true, of course, in classical mechanics.) In particular, the formalism of successive Born approximations gives an expansion of exact scattering amplitudes in powers of charge. This permits making

a definite choice between velocity dependence and LET dependence on theoretical grounds within well-defined limits known from quantum mechanics. As the following analysis shows, the validity of the limits of charge independence of RBE appears to be identical to the limits of the validity of the first Born approximation in collision theory.

Non-relativistically, an incident particle having a charge $+ze$ interacts with an atom consisting of electrons of charge $-e$ and a nucleus of charge $+Ze$ by means of the Coulomb energy operator:

$$V = -\frac{zZe^2}{|\vec{r} - \vec{R}|} + \sum_{j=1}^Z \frac{ze^2}{|\vec{r} - \vec{r}_j|} \quad (3)$$

Here \vec{r} denotes the position vector of the incident particle, \vec{R} that of the nucleus, and \vec{r}_j that of the j th electron. The sum is taken over all electrons ($j = 1, \dots, Z$) in the atom. The transition probability, w_{no} , for excitation of the atom from one state o to another state n with the simultaneous transfer of momentum (and energy) from the incident particle is, in the first Born approximation, proportional to the square of the matrix element of V taken between the initial- and final-state wave functions, ψ_o and ψ_n , of the system, atom-plus-particle. The operator $1/|\vec{r} - \vec{R}|$ has zero matrix element between different (orthogonal) states depending on \vec{r}_j , and so only the second term in equation (3) contributes to w_{no} . The transition probability is proportional to the square of the charge of incident particle:

$$w_{no} \sim |\langle \psi_n | V | \psi_o \rangle|^2 \sim z^2 e^4 |\langle \psi_n | \sum_j \frac{1}{|\vec{r} - \vec{r}_j|} | \psi_o \rangle|^2 \quad (4)$$

where the symbol $\langle || \rangle$ denotes the matrix element for the operators and wave functions shown. The total cross-section σ_i for the interaction of a single incident particle per cm^2 with one atom of type i per cm^3 is calculated by integrating w_{no} over all possible scattering directions and then taking the proper average over initial states and sum over final states of the system. The charge dependence shown in equation (4) is not affected by these operations and so we may write:

$$\sigma_i = z^2 e^4 f(v) \quad (5)$$

where $f(v)$ is a function depending on the velocity, but not the charge, of the incident particle.

The stopping power of the medium is closely related to σ_i . It is calculated by first multiplying w_{no} by the excitation energy of the transition from state o to state n and then carrying out the foregoing operations, after which the result is weighted by the number of atoms N_i of type i per cm^3 in the medium and summed over i . Explicit evaluation of the stopping power² gives an equation of the form:

$$-\frac{dE}{dx} = z^2 e^4 g(v) \quad (6)$$

where $g(v)$ is, for a given stopping medium, a universal function of velocity v for all charged particles. (The function $g(v)$ is given explicitly, for example, by equation (38) of ref. 2.) The expressions (5) and (6) also hold relativistically in the first Born approximation. The inclusion of the second and higher approximations destroys the homogeneity of these expressions in the incident particle's charge ze .

In order to relate the discussion to RBE, a connexion has to be made between the occurrence of a physical collision on a microscopic scale and the occurrence of observable biological damage. We assume that the amount of damage done to a biological system is related to the number of primary quantum transitions or 'hits' which occur between the incident radiation and the target. In keeping with the definition of RBE, we shall assume only that the same extent of damage is produced by two charged radiations (other conditions being the same) when the number of primary quantum transitions per unit volume in the systems is the same. (Since we are considering small targets with uniform dose distribution, this approach is equivalent to relating biological damage to the total number of primary transitions in the system. The volume of the system would then appear explicitly in this description, but would cancel later from both sides of equation (7).) This assumption does not imply a quantitative relationship between degree of damage and number of transitions, but states merely the biological equivalence of two radiations producing the same end-point. This criterion for damage need hold only statistically, because the number of primary quantum transitions leading to observable damage is large.

Since the number of primary transitions per unit volume in a system due to a flux ϕ is $\phi \sum_i N_i \sigma_i$, we describe equal biological damage from two radiations by writing:

$$\phi_1 \sum_i N_i \sigma_{i1} = \phi_2 \sum_i N_i \sigma_{i2} \quad (7)$$

where σ_{i1} and σ_{i2} are the values of σ_i for the two radiations. The resulting flux ratio, when substituted into equation (2) for RBE, gives:

$$\frac{\text{RBE}_1}{\text{RBE}_2} = \frac{\sum_i N_i \sigma_{i1}}{\sum_i N_i \sigma_{i2}} \cdot \frac{(dE/dx)_2}{(dE/dx)_1} \quad (8)$$

The charge dependence of this ratio can be written at once from equations (5) and (6):

$$\frac{\text{RBE}_1}{\text{RBE}_2} = \frac{z_1^2 e^4 \sum_i N_i f(v_1)}{z_2^2 e^4 \sum_i N_i f(v_2)} \cdot \frac{z_2^2 e^4 g(v_2)}{z_1^2 e^4 g(v_1)} = F(v_1, v_2) \quad (9)$$

The explicit dependence on the charges of the incident particles cancels, and it follows that the ratio of RBE values can be expressed as a function $F(v_1, v_2)$ depending only on the velocities of the particles. This is the principal result of the work described here.

While it is true that a highly charged ion causes more damage (that is, a larger number of primary quantum

transitions) than a singly charged one at the same velocity (lower LET), it does not follow that more damage results per unit absorbed dose. Whereas the stopping power of an ion is proportional to z^2 , the flux needed to produce a given number of transitions is proportional to $1/z^2$. The magnitude of the charge acts as a coupling constant for the strength or intensity of the interaction between radiation and matter. Its effect cancels when different radiations are compared on the basis of their absorbed doses, as equation (2) for RBE specifies.

The foregoing results also hold relativistically in the first Born approximation, which coincides with the limits of accuracy of Bethe's original stopping power theory⁶ including various corrections². Physically this means that the theory is valid so long as the speed of the incident particle is much greater than the speed of atomic electrons. For light elements, which are the chief constituent of soft tissue, the first Born approximation, particularly when it includes shell corrections, is known experimentally to give an adequate description of charged particle slowing down for radiation of practical interest in radiobiology. For protons in water, for example, the theory is adequate down to energies of less than 1 MeV (ref. 7). Direct experimental evidence for the possible failure of the first Born approximation appears to have been found only recently, in connexion with the Σ^+ hyperon mass anomaly⁸. The second Born approximation introduces a difference in the stopping powers of positive and negative particles that are otherwise identical. The observed difference is of the order of a few per cent.

In summary, it appears that the validity of charge independence for RBE is equivalent to the validity of the first Born approximation in quantum mechanics. Within the framework of this approximation, the concept of 'LET' dependence for RBE should be replaced by the more precise 'velocity' dependence. Higher-order approximations are needed to describe particles at lower speeds⁹, and charge cannot be factored out and cancelled from the resulting expressions. Experiment indicates, however, that corrections resulting from inclusion of higher-order approximations may amount to only a few per cent.

ADENOSINE TRIPHOSPHATE-METAL-NOREPINEPHRINE TERNARY COMPLEXES AND CATECHOLAMINE BINDING

By DR. ROBERT W. COLBURN and DR. JAMES W. MAAS

Section on Psychosomatic Medicine, Adult Psychiatry Branch, National Institute of Mental Health, National Institutes of Health, Bethesda, Maryland

CATECHOLS and ethanolamines have been shown to form relatively stable chelate bonds¹⁻³, and metals have frequently been associated with catecholamine activity⁴⁻⁸ so that a reasonable approach to the study of

catecholamine binding would seem to be from the point of view of co-ordination chemistry. With the catecholamines a wide variety of chelate species are possible and the different structures would have varied

electrostatic charges and solubilities. Some of these species have recently been elucidated by Walaas *et al.*⁹ in work on Cu(II) chelates of norepinephrine (NE) and epinephrine in connexion with ceruloplasmin. In anaerobic systems the Cu(II) NE chelate was found stable whereas under aerobic conditions oxidation occurred at a moderate rate, which was in agreement with the findings of Chaix *et al.*¹⁰.

In this article results are presented which suggest that co-ordination complexes may be of major importance in the understanding of the biological phenomenon of binding of the catecholamines. This possibility was independently derived by Carlsson *et al.*⁶, but set aside when by paper chromatographic methods sufficient quantities of metals were not found in adrenal medullary particles.

In the work recorded here the levels of metals were determined in sub-cellular fractions of brain known to have high concentrations of the catecholamines. Adult male mice were killed by decapitation, the brains quickly removed, the cerebellum and cerebral mantle dissected away and the remaining brain tissue (the medulla, pons, mesencephalon, diencephalon, hippocampi, and pyriform cortices) was homogenized in 0.32 M sucrose; the technique of Gray and Whittaker¹¹ was used to obtain synaptosomes, and the method of DeRobertis *et al.*¹² was used to obtain synaptic vesicles. In the sub-cellular fractionation the method was slightly modified in that the sucrose (Baker and Adamson reagent grade) was washed with glass-distilled water on a Buchner funnel, dried, dissolved with water to 1.2 molar, and passed over a washed 'Dowex 50' column in the hydrogen form. Succinic acid dehydrogenase (SDH)¹³ and NE levels¹⁴ were determined for the myelin, synaptosome, and mitochondrial fractions to determine the degree of separation of the mitochondria from the synaptosomes. The metals quantitatively measured were magnesium, iron, copper and zinc. For the metal analyses the sub-cellular fractions were dried under vacuum, ashed at 600°C, dissolved in N hydrochloric acid, and measured against standards in an atomic absorption spectrometer (Perkin-Elmer model 303). From the results of these analyses, shown in Fig. 1, it may be seen that in general a good share of the metals in brain are present in the nerve endings. Moreover, while the metals present in this fraction tend to be in proportions similar to the proportions found in brain, copper seems to be concentrated several-fold relative to the

other metals. These findings indicate that the metals magnesium, copper, iron and zinc are present in synaptosomes in sufficient quantities for chelation to be of biological significance.

Metal levels for the synaptic vesicles were determined, in addition, as described above. In this case the metals were again found present in good yield and the level of copper was again noted to be increased relative to the amounts of other metals (Table 1). These findings suggest that metals are present in structures associated with NE rather than with unrelated proteins in the synaptosomes.

Table 1. METAL VALUES FOR SYNAPTIC VESICLES ARE EXPRESSED AS μg PER SYNAPTIC VESICLES OBTAINED FROM 1 g WHOLE BRAIN \pm S.E.M.

Metal	Whole mouse brain ($\mu\text{g/g}$)	Synaptic vesicles ($\mu\text{g/g}$)
Mg	116 \pm 1.7	14.05 \pm 0.29
Fe	51.7 \pm 3.9	1.7 \pm 0.56
Zn	18.7 \pm 0.8	1.05 \pm 0.05
Cu	10.7 \pm 0.5	2.0 \pm 0.16

In summary, both quantities and intracellular location of metals support the hypothesis that co-ordination between metal and NE in the synapse is of biological significance. It therefore seemed of interest to test the effects of a chelating agent on the uptake of exogenous NE. The test materials used were synaptic vesicles rather than synaptosomes and the chelating agent used was ethylenediamine hydrochloride. The control system contained ethylamine hydrochloride at twice equimolar concentration to standardize for ionic effects^{4,15} and possible reactions between amines and quinones even to a limited degree¹⁶. The results obtained in this experiment are shown in Table 2 and the data clearly indicate that the uptake of the exogenous NE was inhibited by this chelating agent. These findings represent additional support, therefore, for chelation as a mechanism for the binding of catecholamines.

Table 2

No addition	0.6 μM <i>d,l</i> -NE	0.6 μM <i>d,l</i> -NE plus 3.2 μM ethylamine hydrochloride	0.6 μM <i>d,l</i> -NE plus 1.6 μM ethylenediamine hydrochloride
14.4*	39.6 \pm 1.4	34.0 \pm 1.1	17.6 \pm 4.0

μg NE in synaptic vesicles after incubation at 0°C for 30 min

Synaptic vesicles were prepared from 4 g whole mouse brain, divided into 4 equal aliquots, and brought to 1 ml. with 0.32 M sucrose + additions as noted. No. = 5 each value. Values are expressed as μg NE \pm S.E.M.

* To obtain this value the NE released from synaptic vesicles during the incubation (3.4 \pm 0.2 μg) was subtracted from the endogenous level without incubation (17.8 \pm 0.8 μg).

Fig. 1. Metal, SDH and NE levels in sub-cellular fractions of dissected mouse brain. NE was determined by a modification of the method of Anton and Sayre (ref. 14). Metal values are expressed as μg sub-cellular fraction obtained from 1 g of original tissue. SDH and NE values as μl O_2 /sub-cellular fraction from 1 g original tissue/h and μg /sub-cellular fraction from 1 g original tissue respectively.

Fig. 2. Potentiometric titration of NE (0.1 mmoles in 10 ml. aqueous solution of 0.1 M KCl, 0.02 M NaCl) with increasing molar ratios of Mg(II) and Ca(II) with carbonate-free 0.1 N KOH

To study the co-ordination chemistry of the metals, magnesium, copper and iron with NE, the method used was potentiometry. This technique was thought best for this survey since it is generally applicable with this class of compounds and since the degree of chelation may be estimated directly from the titration curves. When NE was titrated with and without magnesium in increasing molar ratios it was found that with equimolar magnesium the chelation was negligible at physiological pH, but that with increased molar ratios of magnesium the chelation increased to levels easily of biological significance (Fig. 2). The titration curves for NE with Ca(II) at a molar ratio of 100, shown in addition in Fig. 2, indicate that NE forms somewhat less stable chelates with Ca(II) than with Mg(II). It would be of interest to determine stability constants for NE from the above titration curves, but since chelation may occur at either the catechol moiety or ethanalamine side-chains, additional data are required for such calculations.

For the titration of NE with Cu(II) and Fe(II) it was found necessary to use an organic solvent since the chelates formed were insoluble in water over the pH range examined. The solvent found suitable was water: propanol:butanol 2:3:2, and the electrodes were standardized with *tris* buffer in this solvent. The titration curves obtained in this case with NE and Cu(II) and Fe(II) indicate that at physiological pH, NE essentially completely chelates the metal present even at equimolar metal concentrations (Fig. 3).

In addition it seemed of interest to titrate ATP plus metals with and without NE present, since ATP has recently been found concentrated in synaptosomes¹⁷ and since ATP has been associated with NE storage in many studies^{4,6}. A reasonable hypothesis in this case seemed to be that ATP, metal, and NE might form an ATP-metal-NE ternary complex and that such complexes might be of particular importance in the reaction mechanisms of catecholamines. During the titration of the samples containing Cu(II) and Fe(II) with NE present, it was found that additional protons were released through the pH range 6–8 (Fig. 4). Since NE normally releases

protons only at pH values > 7.5, this, and the formation of an intense blue colour in the case of Fe(II), indicated that a good proportion of the NE was chelated at pH 7.4. The question remaining was whether NE displaced the ATP or chelated with additional co-ordination positions of the metal. It was therefore of interest to note that no precipitate was observed in the samples containing either iron or copper with NE and ATP, whereas a precipitate forms when NE alone is in solution with copper or iron (see foregoing). This finding, in conjunction

Fig. 3. Potentiometric titration of NE in the presence of Mg(II), Fe(II) and Cu(II) (equimolar, 0.05-mmoles in 100 ml. of solvent) with carbonate-free 0.1 N KOH. Solvent system, water: propanol: butanol, 2:3:2

Fig. 4. Potentiometric titration of NE in the presence of various combinations of ATP, Mg(II), Cu(II) and Fe(II) (equimolar, 0.1 mmoles in 10 ml. aqueous solution of KCl, 0.02 M NaCl) with carbonate-free 0.1 N KOH

ATP-NE complex. A unifying concept was then constructed with metal or metal-ATP complexes representing the intravesicular binding sites for catecholamines. The way in which such a hypothesis might explain a variety of reported experimental findings was outlined.

CO-ORDINATION CHEMISTRY AND MEMBRANE FUNCTION WITH PARTICULAR REFERENCE TO THE SYNAPSE AND CATECHOLAMINE TRANSPORT

By DR JAMES W. MAAS and DR. ROBERT W. COLBURN

Section on Psychosomatic Medicine, Adult Psychiatry Branch, National Institute of Mental Health, National Institutes of Health, Bethesda, Maryland

IN an earlier investigation¹ results were presented which indicated that a fraction of pinched-off nerve ending particles (synaptosomes) and synaptic vesicles from brain tissue contained appreciable quantities of copper, iron, and magnesium. The significance of this finding, viewed from the perspective of co-ordination chemistry, for the mechanism of binding of norepinephrine (NE) was discussed. It was also noted that these metals were not freely soluble but tended to be associated with the particulate fraction. This finding suggested that these metals might be co-ordinating with membrane constituents and hence be importantly related to membrane structure and function. Data and theory bearing on this possibility are presented and discussed in this article. In addition, the manner in which such co-ordination structures might be related to the binding and transport of NE is further explored.

Phosphatidyl-L-serine (PS) was obtained from Nutritional Biochemical Corporation, phosphatidyl inositol (PI or fraction I of Folch) and adenosine triphosphate (ATP) as the disodium salt from Sigma Chemical Co. The phospholipids used are constituents of cell membranes in general and have been reported to be present in the membranes of synaptosomes and synaptic vesicles². Sub-cellular fractionation of brain tissue was done as follows: Male rats of approximately 90 days of age were killed, the brains quickly removed, the cerebellum and cerebral mantle dissected away and the remaining brain tissue homogenized in 0.32 M sucrose cleaned of metals as previously noted¹. The technique of Whittaker^{3,4} was used to prepare a fraction of synaptosomes. Evidence that this fraction was composed of synaptosomes was obtained by a spot check of succinic acid dehydrogenase activity (SDH)⁵ and NE content⁶ of the myelin, synaptosome, and mitochondrial fractions. The SDH activity in μ 10₂/g original tissue/h was 18, 60 and 793 respectively. NE values in μ g/g original tissue were found to be myelin: 7.5; synaptosomes, 52; and mitochondria, 41.5. It is assumed that the NE levels for the mitochondrial fraction represent a contamination by synaptosomes. Lipid extracts of pellets of synaptosomes were prepared by the method of Folch, Lees, and Sloane-Stanley⁷. An upper phase non-lipid fraction was also obtained by this method. This fraction is hereafter referred to as 'upper phase extract of synaptosomes'. The fractions were evaporated to dryness and resuspended

in water. Titrations and metal determinations were carried out as previously noted¹. The solubility characteristics of various metal complexes in aqueous-ether phospholipid dispersions were obtained as follows: The combination of compounds to be examined were added in noted amounts to glass-distilled water and then the particular metal being used was added and the total volume brought to 1 ml. The pH was then adjusted to 7.3 with sodium hydroxide. This aqueous phase was then overlain with 3 c.c. of diethyl ether, the tubes capped, shaken for 15 min, and centrifuged at 2,500 r.p.m. for 15 min. At this point the colour of the ether phase was noted and 0.4 c.c. of the ether phase was removed for metal assay. If NE values were to be determined, tritiated *d,l*-NE (New England Nuclear Corp.) was mixed in tracer amounts with cold *d,l*-NE in noted quantities. C.p.m. were determined from both aqueous and ether phases using a Packard liquid scintillation spectrometer, and partition coefficients calculated as:

$$\frac{\text{c.p.m./c.c. ether phase}}{\text{c.p.m./c.c. aqueous phase}}$$

The results obtained may be summarized as follows. When phosphatidyl-L-serine is titrated in the presence of Mg(II), Cu(II) or Fe(III) the curves obtained indicate co-ordination of these metals with the phospholipid (Fig. 1). Moreover, evidence for complex formations between metal and phosphatidyl-L-serine altering the physical characteristics of the components is indicated in Table 1, in which it is noted that the metal content of the ether phase increases. If ATP is added to the phosphatidyl-L-serine metal complex it is found that: (a) precipitation does not occur; (b) the metal is not found in the ether phase (Table 1). The ATP effect might occur owing to the formation of co-ordination complexes between metal and ATP with no metal being available for the phospholipid. However, titration data as shown in Fig. 1, taken in conjunction with solubility characteristics (Table 1), suggest that a ternary metal-ATP-PS co-ordination complex forms. More explicitly, when PS is added to Fe(III) ATP solutions, Cu(II) ATP solutions or additional protons are released. This could occur owing to the formation of a ternary complex or the displacement of ATP by the phospholipid. If the latter were the case,

however, due to alterations in solubility, one would expect to find significant quantities of Fe(III) in the ether phase (Table 1). That this does not occur supports the argument for ternary complex formation between Fe(III), ATP and phospholipids. Moreover, in titrations (not shown) of metal, PS, and ATP in aqueous solutions (0.1 N KCl, 0.05 N NaCl) a precipitate did not form whereas precipitation did occur if only metal and the phospholipid were present. Owing to the physical characteristics of Mg(II), evidence for ternary complex formation from Mg(II) titration data is less firm than in the case of Fe(III) and Cu (II). However, if magnesium were present in greater than equimolar concentrations, as might occur in biological systems, then by the law of mass action increased complex formation would occur, as was shown for the case of Mg (II) and NE in an earlier report¹. The increased solubility of the metal-phosphatidyl-1-serine-ATP complex in water and decreased solubility in ether is thought to be a function of the quadrivalent ATP. The presence of a ternary complex is not too surprising as ATP is known to form a chelate structure $M(ATP)^{8-12}$ and the serine group could easily form a 5-membered chelate ring utilizing the remaining co-ordination positions of the metal. In terms of overall electrostatic charge, alterations in solubility may be understood.

Table 1

Metal	5.00 μ M phosphatidyl-1-serine		5.00 μ M phosphatidyl inoside		No phospholipid
	Without ATP	6.25 μ M ATP	Without ATP	6.25 μ M ATP	
6.25 μ M $CuCl_2$	2.32 \pm 0.64	0.016 \pm 0.002	1.66 \pm 0.021	0.071 \pm 0.005	0
6.25 μ M $FeCl_3$	0.68 \pm 0.32	0.025 \pm 0.002	0.88 \pm 0.76	0	0
6.25 μ M $MgCl_2$	0.59 \pm 0.18	0.03 \pm 0	1.16 \pm 0.29	0.087 \pm 0.005	0

Values refer to μ M metal/3 ml. of ether \pm S.E.M. The No. for all metals + phospholipid is 3 and for all metals + phospholipid + ATP is 2.

As can be seen from Table 1, in the presence of phosphatidyl inoside metal is found in the ether phase in increased amounts. Titration results (Fig. 2) suggest the presence of a metal-phosphatidyl inoside co-ordination complex. It is also noted that, as before, metal incorporation into the ether phase is essentially reduced to zero in the presence of ATP. Evidence from titration data (Fig. 2) and solubility characteristics (Table 1) suggest the formation of a ternary co-ordination structure between metal, ATP, and phosphatidyl inoside. The dissociation characteristics of phosphatidyl inoside are such that the titration data with this phospholipid more clearly suggest

Fig. 1. Potentiometric titration of phosphatidyl-1-serine in the presence of various combinations of ATP, Mg(II) and Cu(II) (equimolar, 0.01 mmoles in 100 ml water isopropanol-*n*-butanol, 2:3:2) with carbonate-free 0.1 N KOH. Samples containing Fe(III) were equimolar with the other components at 0.01 mmoles

Fig. 2. Potentiometric titration of phosphatidyl inoside in the presence of various combinations of ATP, Mg(II), Cu(II) and Fe(III) (equimolar, 0.01 mmoles in 100 ml water isopropanol-*n*-butanol, 2:3:2) with carbonate-free 0.1 N KOH

ternary complex formation for Cu(II) and Mg(II) as well as Fe(III).

Although the co-ordination structures of these phospholipid-metal complexes are not clear it does seem that the structures are sufficiently stable in the presence of water to alter the solubility characteristics of the metal-phospholipid complex.

The two phospholipids thus far mentioned were chosen because of differences in their polar groups as well as being naturally occurring membrane constituents. It is not felt, however, that the change in solubility characteristics induced by metal complexes need be limited to these two. Any molecule which can co-ordinate stably with metal with an alteration in overall electronic structure would be expected to exhibit the characteristics shown by the two phospholipids examined. This phenomenon is well known, namely, precipitation of amino-acids by Cu(II), the inner complex salt of Werner¹³.

To be certain that the results and theory constructed from them would be applicable to the central nervous system, lipids were extracted from a pellet of the synaptic fraction of an ultra-centrifugate of dissected brain. As a control the upper phase as defined by Folch, Lees and Sloane-Stanley⁷, which contains predominantly water-soluble material, was used. The ability of this lipid extract to increase the incorporation of metals into the ether phase and a prevention of this by the presence of ATP are shown in Table 2. This was not found with upper phase material, which is taken as suggesting that lipids from biological material, synapses, will co-ordinate with metals and alter their electronic structure. Further, in the light of preceding data it seems reasonable to assume that ternary complexes form between synaptic lipids, metal, and ATP.

It is of interest that Folch, Lees, and Sloane-Stanley⁷ find that $MgCl_2$ 0.003 N, $CaCl_2$ 0.003 N, $NaCl$ 0.05 N, KCl 0.05 N are able to alter the distribution of lipids between the upper and lower phases, that is, the metals increase the yield of lipids in the lower, chloroform phase. Wolman and Wiener¹⁴ report that when myelins

Table 2

	Lipid extract of synaptosomes Without ATP	6.25 μ M ATP	Upper phase extract of synaptosomes	No. extract
6.25 μ M $CuCl_2$	1.17 \pm 0.126	0.012 \pm 0.001	0	0
6.25 μ M $FeCl_3$	0.61 \pm 0.022	0.035	0.023 \pm 0.0071	0
6.25 μ M $MgCl_2$	0.086 \pm 0.013	0.025 \pm 0.005	0	0

Values are expressed as μ M metal/3 c.c. ether/mg extract (dry weight) \pm S.E.M.; No.=4 (approximately 1 mg dry wt of lipid extract was used per tube, approximately 4 mg dry wt. of 'upper phase' extract was used per tube) 11 mg of the lipid extract of synaptosome before addition of metals was found to contain 0.005 μ M Cu, 0.0048 μ M Fe, and 0.037 μ M Mg.

are homogenized in 0.5 M calcium chloride an aqueous extraction yields only small amounts of lipid. They interpret this as indicating that the Ca^{++} has induced a transition of phospholipids to a water-in-oil pattern (Fig. 3). West¹⁵ also notes the ability of metals to induce this transition. Others have suggested a role for membrane phospholipids in ion transport^{16,17}. These investigators, however, have used the concept of electrostatic, attractive forces to explain the effect of metals on polar lipids. It is suggested here that the use of the theory and facts of co-ordination chemistry is more appropriate for the understanding of interactions between membrane phospholipids and metals as this body of knowledge: (a) aids in the understanding of differences in behaviour of various cations; (b) allows the introduction of steric considerations; (c) suggests that relatively stable complex formation (such as chelation) may occur between membranes and metals with an alteration in their solubility characteristics; (d) raises the possibility of ternary complex formation between a membrane constituent, metal, and biologically active molecules, namely, ATP amino-acids, metal activated enzymes. This latter point is of particular importance because of the well-known relationship between ATP enzymes and the maintenance of membrane function.

The results so far presented may be interpreted as follows. Phospholipids alone dispersed in aqueous systems are oriented with their polar heads towards the aqueous phase (in either lamellar sheets or globular arrays). In the presence of metals co-ordination complexes between the metal and phospholipids form which alter the electronic structure of the complex in such a way that a portion of the phospholipid dispersion assumes a water-in-oil configuration (Fig. 3) and hence the increase in ether solubility of the metal-phospholipid complex. If one adds ATP, however, the situation is quite different. Owing to either the formation of ternary complexes or the functional removal of metal by ATP the phospholipid dispersions are shifted towards a predominantly oil-in-water pattern. In this system metals and ATP have a role as important modulators of the configurational array assumed by phospholipids in aqueous systems.

The significance of this for biological membranes is suggested to be as follows. Metal-ATP-phospholipid complexes can be seen as forming lamellar sheets in agreement with the most generally accepted model depicting the cellular membrane¹⁸⁻²² as composed of two unimolecular lipoprotein leaflets having the phospholipid molecules so oriented that the hydrocarbon tails point

toward each other. However, if the ATP is removed, by ATPase, for example, the electronic structure of the metal-phospholipid complex will favour the development of a quite different configuration. Replacement of the ATP, by a metabolic source, will lead to a resumption of the usually depicted lamellar configuration. In the understanding of membrane function in nerve, some mechanism, whereby rapid reversible alterations in membrane structure occur, is necessary. How such a mechanism might operate in a bio-logical system, such as a synapse, is presented in Fig. 4. If such a model is correct, the following can be predicted.

(1) Whether on the inner or outer surface of the cellular membrane, metals will tend to induce configurations of the water-in-oil type, that is, to produce a mosaic of water-filled channels or pores lined with charges. The dimensions of these pores may easily²³ be of sufficient size to permit the passage of ions and small molecules across the membranes. Larger molecules which can co-ordinate with the sterically available metals may cross the membrane in an exchange reaction.

(2) The pores in this model have fixed charges and varying dimensions of a type dependent on the particular phospholipid and metal involved. They could thus assume the properties of permselective membranes²⁴. In this respect it is of interest that copper converts the frog skin membrane into a structure which becomes selectively impermeable to chloride ions²⁵.

(3) It is generally agreed that ATP is quite important in membrane function and is known to be present in the *milieu interieur* of the cell and synapse; for example, Nyman and Whittaker²⁶ have shown that a stable ATP fraction which is probably only about 10 per cent of that found *in vivo* is present in synapses in a molar concentration some 200 times greater than serotonin. From our results it is suggested that complexes between ATP-metal-phospholipids would tend to maintain the lamellar arrangement, and as the metabolic source of ATP is in the interior of the cell this will lead to different structural configurations between the inner and outer surfaces of the membrane, that is, there are many less water-in-oil configurations on the inner surface. This would mean that in the presence of ATP the energy barrier to passage of small ions such as sodium or potassium and larger molecules in either direction across the internal interface would be relatively large, that is, selective ion concentrations and hence potential gradients would tend to be maintained as well as there being a barrier to the passage of polar molecules.

Fig. 3. Schematic representation of oil-in-water and water-in-oil patterns

(4) Removal of ATP from the ATP-metal phospholipid complex as by ATPase, which may be intimately associated with membrane function in nerve²⁷, would result in the internal surface of the membrane spontaneously assuming a water-in-oil configuration, that is, one would now have a mosaic of charged pores both on the inner and outer surfaces of the membrane with consequent fluxes of water and ions across the membrane in both directions. Two especially interesting features predicted from this are: (a) the loss of the membrane potential due to Na^+ and K^+ exchange; (b) a change in membrane resistance.

(5) Replacement of ATP on the metal-phospholipid groups would result in a resumption of the resting structure, that is, one without pores on the inner surface and an energy barrier to movement of ions and larger molecules across it. Without a steady supply of ATP this resumption would not occur and the membrane would progressively, functionally deteriorate.

(6) Some miscellaneous features of the model to be noted are as follows: Luzzati and Husson²⁸ have shown that the phospholipids extracted from brain, at body temperature, are not in a coagel but a liquid crystalline state, that is, at 37° the hydrocarbon tails have melted. As such the energy barrier of the hydrocarbon tails to transitions between the two configurations would be less than with a coagel. Furthermore, they have found by X-ray diffraction data that such water-in-oil to oil-in-water transitions can spontaneously occur in phospholipid-aqueous dispersions depending on concentration. As such, counter forces in either direction could be quite determinant as to the configuration assumed.

It is of interest that Baker, Hodgkins and Meves²⁸ have raised the possibility of there being fixed negative charges on the inner surface of the membrane which they relate to ionized phospholipid and carboxyl groups. Quadrivalent

ATP might significantly contribute to such fixed negative groups.

Other, less metabolically active, molecules might also function as ATP in the maintenance of the oil-in-water configuration and would tend to stabilize the membrane in this form. Attention has been focused on ATP because of the importance of its production and dephosphorylation for normal membrane function.

Data and theory bearing on a mechanism whereby a neurotransmitter, norepinephrine, might be released from the pre-synaptic terminal are now presented. In the preceding article it was noted that metals found in the synaptosomes and synaptic vesicles tended to remain with the particulate fractions and not enter the supernatant. Further, evidence for the formation of metal-NE chelate structures and their importance in storage pools within synaptic vesicles and synaptosomes was discussed. In the light of results presented in the earlier portion of this article, it seems possible that ternary complexes might form between membrane phospholipids, metals, and NE or even quaternary complexes with ATP where the co-ordination number of the metal is 6 or more.

Titration curves (Fig. 5) suggest that such ternary complexes do occur between phosphatidyl-1-serine, metals and *d,l*-norepinephrine.

Solubility characteristics of metals and NE in the presence of two phospholipids are presented in Table 3. It is noted that in the presence of metals and phospholipids the quantities of metal in the ether phase and the partition coefficients of NE are markedly altered. A NE-metal-phospholipid complex is thus seen to have altered solubility characteristics such that a polar NE molecule becomes more soluble in an organic solvent. Phrased differently, the energy barrier to the movement of NE into an organic solvent is reduced by complexing. This might be of significance in understanding a mechanism

Fig. 4. Schematic representation of suggested cell membrane transitions as outlined in the text. (The letter *M* represents metals. Filled black circles indicate membrane components which form relatively unstable co-ordination complexes)

Fig 5. Potentiometric titration of phosphatidyl-1-serine in the presence of NE, Mg(II), Cu(II), and Fe(III) (equimolar, 0.01 mmoles in 100 ml. water: isopropanol: *n*-butanol, 2:3:2) with carbonate-free 0.1 N KOH

whereby a polar molecule such as NE moves across the potential energy barrier of the lipid membrane.

In Table 4 data on the effects of salt concentrations on metal concentrations in the ether phase and NE partition coefficients are presented. It is noted that there is a marked effect in general but that this is independent of the ion species, that is, sodium and potassium do not

cause differential effects. The changes noted are felt to be a function of the salts increasing the polarity of the aqueous phase with a consequent accentuation of solubility characteristics. This raises the possibility that in biological systems the solubility changes reported throughout this article would be accentuated.

In Table 5 it is noted that increasing concentrations of ATP progressively diminish the amount of metals found in ether as well as decreasing the partition coefficients of NE. Possible co-ordination complexes by which this might occur are several, but the important point is that the presence of ATP could serve as an important modulator of the amount of NE which is able to surmount the energy barrier represented by the membrane.

Finally, similar effects of lipid extracts of synaptosomes and upper phase extracts are presented in Table 6. It is noted again that the presence of the lipids increases both partition coefficients and metal content of the ether phase and that this is inhibited by ATP.

From these results the following hypothesis regarding synaptic membrane function and NE is suggested. In the resting membrane the presence of ATP increases the energy barrier to the movement of NE across the internal surface of the membrane. If ATP is removed, as by an ATPase, either (a) unfilled co-ordination positions on the metal-phospholipid become available to NE, or (b) the removal of ATP from a quaternary complex occurs and a ternary phospholipid-metal-NE complex remains. In either case, the electronic structure of this ternary complex is such that its solubility in the aqueous phase is decreased, whereas in the lipid phase (the cell membrane)

Table 3
Metal content is expressed as $\mu\text{M}/3$ c.c. ether \pm S.E.M. (No.=3 to 5; N.D. means not done)

its solubility is increased. The net result is an increase in movement of NE across the cell membrane. The mechanism of movement of the NE molecule is not clear, that is, it might occur simply as an exchange reaction or be a function of the development of a water-in-oil pattern which sterically would place the NE molecule in the membrane pore as outlined in an earlier part of this article. Displacement of NE by ATP (from a metabolic source *in vivo* or an exogenous source *in vitro*) would bring about a resumption of the usual resting structure. Note that by this mechanism the membrane ATP will tend to prevent loss of NE from the vesicle and that a steady supply of ATP is necessary to prevent the vesicle from functionally deteriorating.

Table 6

		Lipid extract of synaptosomes + 6.25 μ M NE		Upper phase synaptosomes + 6.25 μ M NE
		Without ATP	6.25 μ M ATP	
6.25 μ M CuCl ₂	Partition coeffi- cient NE	0.046 \pm 0.017	0.003 \pm 0.001	All values < 0.001
	Copper content	0.320 \pm 0.113	0.0155 \pm 0.0027	0
No copper	Partition coeffi- cient NE	0.0027 \pm 0.0014	—	All values < 0.001

Metal content is expressed as μ M Cu/3 c.c. ether/mg extract (dry wt.) \pm S.E.M. with No. = 5 or 6. Approximately 1 mg (dry wt.) of lipid extract was used per tube; approximately 4 mg (dry wt.) of upper phase extract was used/tube.

The report²⁸ that cold NE can be taken up against a gradient by granules known to be rich in this amine can be satisfactorily explained by the presence of metals within the granules¹. In addition, reports^{29,30} suggest magnesium and ATP are necessary for uptake of NE or E by chromaffin granules. The great bulk of the data reported by these investigators involved rate curves for the appearance of radioisotopically labelled catecholamines within the granules. As such, any factor causing an increase in endogenous pool size would lead to a less rapid exit of the isotopically labelled molecule and hence higher c.p.m. As noted before¹, we feel that there is a true uptake, against a gradient, owing to the presence of metals within the granules, but that in addition the presence of magnesium and ATP diminishes the rate of

outflow of NE from the interior of the vesicle for reasons which follow from the suggested role of ATP and metal in membrane function and NE transport. The combination of true uptake against a gradient due to metal within the vesicle and diminished outflow due to magnesium-ATP then leads to greater amounts of radioactivity being found within the granule.

ACETOHYDROXAMATE: BACTERIAL UREASE INHIBITOR WITH THERAPEUTIC POTENTIAL IN HYPERAMMONAEMIC STATES

By DR. WILLIAM N. FISHBEIN and PAUL P. CARBONE

Medicine Branch, National Cancer Institute

AND

H. DONALD HOCHSTEIN

Clinical Pathology Department, Clinical Center, National Institutes of Health, Bethesda, Maryland

DURING investigations demonstrating that the anti-leukaemic agent, hydroxyurea, is both a substrate and an inhibitor of jackbean urease¹⁻³, acetohydroxamic acid (AHA) was used as an analogue of hydroxyurea. AHA was found to be an irreversible, non-competitive urease inhibitor with a rate constant of $10^3 \text{ M}^{-1} \text{ min}^{-1}$ at 25° C, that is, 1 mmole AHA produced complete urease inactivation in 3-4 min⁴. Since the compound has little toxicity for animals⁴ and has been shown to exert no inhibitory effects on a variety of other enzyme systems⁵, it was examined for possible clinical application in treating hyperammonaemic states by reducing the contribution to blood ammonia by intestinal urease activity. The need for such an agent has been expressed elsewhere^{6,7}. The work described here establishes the inhibitory effect

of AHA on bacterial urease *in vitro* and *in vivo*, and reports the effect of the compound in a single patient with liver disease.

Following preparation and purification of AHA⁸, a preliminary assessment of excretion and acute toxicity was made. Intraperitoneal administration of a single dose of 900 mg/kg to each of three adult rats resulted in no gross clinical disturbances over a one-month observation period, and the full dose was recovered (98, 100 and 110 per cent) in the urine excreted during the first 24 h, as determined by ferric chloride assay². Although this assay method is not definitive (it would not, for example, discriminate AHA from other hydroxamic acids that might occur as biological derivatives), the results suggest that AHA is rapidly and, in contrast

hydroxyurea⁸, completely excreted. Five mmoles HA (375 µg/ml.) in trypticase soy broth produced no growth inhibition in tetracycline-sensitive strains (0.2–5 µg/ml.) of *Staphylococcus aureus*, β-haemolytic *Streptococcus* Group A, *Escherichia coli*, *Klebsiella* sp., *Pseudomonas aeruginosa*, *Proteus mirabilis*, *Brucella* sp., and *ordetella* sp. Unlike hydroxyurea, which regularly inhibits the growth of *Pseudomonas* organisms⁹, AHA appears to be devoid of antibacterial activity despite a very similar chemical structure.

Urease inhibition by AHA was evaluated for the same organisms (excepting the *Streptococcus* and *E. coli*) in standard bacteriological media¹⁰, which contain a highly buffered solution of urea at a concentration approximating that of urine. Gradation of the colour change of the phenol red indicator produced by the alkaline ammonium carbonate liberated from urea serves as a convenient index of the degree of urea decomposition. In all six species, AHA, at concentrations of 1 mmole or less, significantly inhibited the ureolytic activity. Fig. 1 illustrates the data for *Klebsiella* sp. and *Proteus mirabilis*.

In one experiment a duplicate set of cultures was used, omitting the indicator; aliquots were acidified, Seitz-filtered, diluted and analysed directly for urea¹¹. The inhibition is more impressively demonstrated by this method, and the correlation of urea decline with indicator changes is evident (Fig. 1). Since saturating levels of urea are present in these experiments, the non-competitive nature of AHA inhibition is further substantiated, and suggests that the action of the drug would not be compromised by even the high urea concentrations of urine. The ultimate appearance of ureolytic activity in the media containing AHA may simply reflect the unchecked bacterial growth.

AHA inhibition of bacterial urease activity *in vivo* was assessed in adult rats by the use of ¹⁴C-urea¹². Twenty-five µc. of the isotope was injected subcutaneously immediately after intraperitoneal injection of AHA. The animal was placed at once in a metabolic chamber¹³ and

Table 1. PERCENTAGE OF ¹⁴C-UREA EXPIRED AT ¹⁴CO₂ IN RATS GIVEN A 25-µc. DOSE SUBCUTANEOUSLY IMMEDIATELY AFTER INTRAPERITONEAL ADMINISTRATION OF AHA

The figures in parentheses denote percentage inhibition during the individual collection periods relative to the control values

		Tetra-cycline				

the expired carbon dioxide was collected in 4 N NaOH, aliquots of which were counted directly in a liquid scintillation spectrometer by the two-phase anthracene method of Steinberg¹⁴. The radioactivity of expired carbon dioxide amounted to about 3 per cent of the administered dose of urea per h in the control animals (Table 1); it was reproducible, and was consistent with the values obtained by others in mice^{15–17}. AHA, at doses of 20–50 mg/kg, resulted in a 70 per cent inhibition of urea decomposition during the first 3 h. In the experiment involving hourly collections, the inhibition seems to begin to decline in the third and fourth hours. The lesser degree of inhibition occurring when a large dose of tetracycline is substituted for AHA may be reasonably presumed to be due to the different modes of action of the two drugs. AHA directly inhibits urease without any demonstrable concomitant antibacterial activity (which, incidentally, suggests that under the particular conditions involved, urease is functioning as a 'scavenger' enzyme rather than in any essential metabolic sequence). On the other hand, the antibiotics, although capable of completely suppressing *in vivo* urease activity, do so not by any direct action on the enzyme, but by suppressing bacterial growth^{17,18}. The short time-interval used in these experiments, therefore, does not permit the indirect action of tetracycline to reach maximum effect. Interestingly, complete suppression of ureolysis by AHA was not attained even at high dose levels. While the reason for this is not clear, it may possibly represent persistent gastric urease activity owing to failure of the enzyme-inhibitor complex to form under acid conditions⁵.

Although urine collections over these brief periods are subject to considerable error, urinary radioactivity in these experiments approximated 13 per cent of the injected dose per hour. The fraction of acid-labile radioactivity was within the error of determination for both the ¹⁴C-urea reagent (1 per cent) and all urine specimens (5 per cent).

While AHA seems clearly to be an effective inhibitor of bacterial urease, a more critical question concerns the feasibility of using this agent as a drug to lower elevated blood ammonia-levels. Since the compound is not generally available, and chronic toxicity examinations will probably consume large quantities of it, a preliminary trial of the compound was made in a single patient to assist in deciding whether a full-scale investigation should be undertaken¹⁹. The patient, a 60-year-old male with chronic myelogenous leukaemia and leukaemic infiltration of the liver, had received an end-to-side portocaval shunt nine months before to relieve jaundice and hepatic coma consequent to portal vein thrombosis. At the time of this investigation, his haematological status was stable, despite elevated platelet and white cell counts; his liver functions were entirely normal save for elevated blood ammonia-levels. The patient was maintained at bed-rest

Fig. 1. Inhibition of bacterial ureolytic activity by AHA in urea broth cultures. The colour changes of phenol red indicated produced by alkaline ammonium carbonate liberated from urea are graded 1 to 4+. Direct measurement of urea was also performed. See text for details

and fasting until 2 p.m. each examination day and received the drug orally in capsule form, with half of each dose being enteric-coated. Antecubital vein blood was withdrawn without stasis via an indwelling Cournand needle, and blood ammonia determinations were performed immediately, in duplicate, by the method of Seligson and Hirahara²⁰. The results are shown in Fig. 2; the decline and return of blood ammonia-level following the larger dose of AHA, while certainly suggestive, are not definitive because of the wide physiological and/or measurement fluctuation apparent during the control day. It would seem unlikely that the absence of a striking decline in ammonia-level is due to inactivity of oral AHA in man, since the drug, in this instance, is acting, not on host enzymes, but on those of bacteria in the alimentary canal. It seems more reasonable to presume that, at least in this particular case, bacterial urease is not playing a decisive role in maintaining elevated blood ammonia-levels. While it is clear that urea nitrogen can be used in anabolic processes^{21,22} and that the administration of urease and/or urea can produce ammonia intoxication^{7,23,24}, the fraction of total blood ammonia-levels in man attributable to urease, as compared to other bacterial and host ammonia-generating enzyme systems, has never been evaluated. A combination investigation using ¹⁴C-urea, a specific urease inhibitor such as AHA, and antibiotics might provide an answer to this question. The limiting factor in such an approach, at present, is the variability in blood ammonia determinations²⁵. In the patient examined, for example, if the maximum decline in blood ammonia on day five was taken literally as due to AHA, then, assuming 70 per cent urease inhibition at this dose, the fraction of the stable blood ammonia contributed by this 'exogenous' enzyme would be an impressive 35 per cent. Yet this degree of decline in blood ammonia is still not a conclusive change.

No symptoms attended the administration of AHA to this patient, and no effects on the haemogram or hepatorenal function tests were observed during a five-day hospital observation period. Since the toxic effects of chemically related compounds occur and subside quickly in relation to drug administration and withdrawal^{26,27}, more extensive trials of AHA in man would appear practicable.

The present data indicate that further investigation of AHA to define its clinical potential is warranted. Since urease inhibition is a general feature of hydroxamic acids⁵, it is, of course, possible that another of these compounds may ultimately be found to be more suitable. AHA was selected by us because of information available regarding its specificity and low toxicity. Like AHA, hydroxyurea is also an irreversible urease inhibitor, but, unlike AHA, a residual fraction of enzyme activity does persist in its presence³. Hydroxyurea is decomposed by urease with

the liberation of ammonia, while AHA is inactive as substrate^{1,2}. Hydroxyurea produces extensive chromosomal breakage in cultures of hamster and mouse embryo cells²⁸ and of normal human leucocytes²⁹, while AHA is inactive in this regard²⁹. The problem of megaloblastosis attending hydroxyurea treatment^{30,31} may yet turn up, on extensive toxicity investigations with AHA, but on the basis of available knowledge, the latter compound would seem to offer a definite superiority as a urease inhibitor in man.

AHA appears to possess most of the characteristic desirable in an ideal anti-urease drug. (a) Its inhibition is specific, complete, and irreversible and occurs via complex formation rather than by oxidative phenomena^{3,4}. (b) It can be expected to be free of allergic danger attending the use of urease antibodies⁶. (c) Its action would complement, rather than mimic, that of antibiotics. In addition to the most evident applicable clinical situation, hepatic failure, it is possible that hyperammonaemia may play a part in the acute morbidity of certain septic caemias, consequent to the urease activity present in many bacterial pathogens³² in combination with hepatic anoxaemia. If so, a urease inhibitor might be of value in the initial critical phase of treatment, until antibiotic control of bacterial growth has been attained.

RAPIDLY LABELLED SYNTHESIS OF RIBONUCLEIC ACID IN EHRlich ASCITES C-2 TUMOUR CELLS TREATED WITH ACTINOMYCIN D

By DUŠAN A. POPOVIĆ

Institute for Medical Research, Novi Sad, Yugoslavia

ACTINOMYCIN D markedly inhibits DNA-dependent RNA polymerase, and inhibits DNA-primed RNA synthesis *in vitro* and *in vivo*^{1,2}. This biological activity is correlated with its ability to form complexes with DNA-guanin residues³. There are more types of DNA-actinomycin D binding sites *in vitro*⁴, and the synthesis of ribosomal and s-RNA *in vivo* is more sensitive⁵ than the synthesis of DNA-like RNA⁶. A rapid turnover of messenger RNA⁷ was originally thought to be a characteristic of this class of material, and may be defined, so far as is known at present, as a sequence-determining template in ribosomes for catalytic function in protein synthesis⁸. But in mammalian cells it is not clear how the transfer messenger RNA of the labelled nuclear RNA is related to the stable cytoplasmic RNA⁹. When cells were incubated for 10 min with ¹⁴C-adenine, then transferred to a non-radioactive medium containing actinomycin D, the pulse-labelled nuclear RNA underwent breakdown to acid-soluble end-products in the nucleus, no transfer of the pulse-labelled RNA from nucleus to cytoplasm could be detected¹⁰⁻¹³. On the other hand, when the cells were exposed to ¹⁴C-adenine for 20 min and the radioactive precursor remained in the medium, after adding actinomycin D, experiments demonstrated the transfer of the labelled nuclear RNA to the cytoplasm¹⁴. The radioactivity may continue to be incorporated into both nuclear and cytoplasmic RNA at the highest rate 3-4 h after addition of the actinomycin D (ref. 14). In our work we found the same difference between 'normal' pulse-labelled RNA and the 'second' pulse-labelled RNA when the cells were treated for 4-5 h with actinomycin D. In contrast to the 'normal' pulse-labelled, the 'second' pulse-labelled RNA passed quickly into the cytoplasmic compartment, and also exhibited other differences.

Ehrlich ascites mouse tumour cells C-2 were grown as described previously¹⁵. A suspension of cells (500 mg dry weight) in Oerle medium (95 per cent O₂-5 per cent CO₂ at 37° C) were exposed for 10 min to uracil 2-¹⁴C, 1 μC./ml. After labelling, the cells were washed with physiological saline and re-incubated in non-radioactive Oerle medium (5 μg/ml.) actinomycin D. Cells were taken after 15 min, and at intervals thereafter for 5 h. The respective fractions were denatured by acidification to 0.5 N PCA, washed once more with 0.4 N PCA, and neutralized with 1 N KOH using phenol red as an internal indicator. RNA was isolated with 10 per cent NaCl and subsequent ethanolic precipitation¹⁷. Following alkaline digestion with 0.4 N KOH for 17 h at 37° C the resulting ribonucleotides were separated by column procedure on 'Dowex-1' HCOO⁻ x-10 200-400 mesh¹⁸. The specific activities of RNA pyrimidines were determined in peak portions (0.1-0.2 μM) in a Nuclear Chicago assembly operating with a thin-window counter. The specific activities were expressed as c.p.m./μmole, based on the extinction coefficients given by Cohn¹⁹. The total error of the measurements by the parallel samples never exceeds ± 5 per cent.

During the 5 h more than 90 per cent of the radioactive pyrimidines is released from the total RNA to the acid-soluble end-products¹⁰⁻¹³. Residual radioactivity seems to come from heterogeneous RNA in a stable form. In this system we have studied various nucleic acids after 'normal' pulse-labelling and 'second' pulse-labelling 4-5 h later. Aliquots of cells were enucleated by controlled stirring in a solution of 'Tween 80' (ref. 20) and the nuclear nucleic acids were separated with 1 M NaCl (ref. 21). These cytoplasmic fractions, 1 M NaCl nuclear

extractable, and 1 M NaCl residual nuclear RNA, were treated for the specific activity of pyrimidines as described previously.

After the first pulse-labelling the earliest labelled RNA is extractable from nuclear RNAs with 1 M NaCl. In the

Fig. 1. Ehrlich ascites tumour cells C-2 were exposed to ¹⁴C-uracil for 10 min. They were then washed and transferred at zero time to non-radioactive medium containing actinomycin D at a concentration of 5 μg/ml. Specific activities of total RNA pyrimidines (Cp + Up) were determined for 6 h.

Fig. 2. Ehrlich ascites tumour cells C-2 were exposed to ¹⁴C-uracil for 10 min. They were then washed and transferred at zero time to non-radioactive medium containing actinomycin D at a concentration of 5 μg/ml. for 4-5 h. The cells were washed and re-incubated for 10 min in ¹⁴C-uracil. Specific activities of Cp + Up were determined for . . . cytoplasmic RNA, — nuclear 1 M NaCl extractable RNA, - - - nuclear 1 M NaCl non-extractable RNA.

nuclear residual and cytoplasmic RNAs no radioactivity was determined. After the second pulse-labelling (DNA primed and dependent RNA synthesis was abolished with actinomycin D and 'normal' pulse-labelled RNA was degraded to an acid-soluble end-product), both the residual nuclear and cytoplasmic RNA were labelled. No radioactivity was found in the nuclear 1 M NaCl-extractable RNA.

Our results suggest the possible role of the 'normal' pulse-labelled RNA on the other biosynthetic routes. There is some difference between 'normal' pulse-labelled and 'second' pulse-labelled RNAs: 'normal' 10-min-labelled RNA is nuclear 1 M NaCl-extractable; 'second' 10-min-labelled RNA is not, and a possible interpretation is that it more quickly passed into the cytoplasmic compartment.

The 'second' pulse-labelled RNA seems to be of chromosomal origin; the nuclei treated with 'Tween 80' have no nucleoli²². These results point to an RNA-dependent biosynthetic route in Ehrlich ascites cells²³.

The present investigations demonstrate that there are more 'pulse'-labelled RNAs and demonstrate the transfer of messenger RNA from the nucleus to the cytoplasm.

I thank Prof. H. Harris for his advice, and Merc Sharpe and Dohme, Inc., for the gift of actinomycin D.

MICROMETHOD FOR MEASURING MICROBIAL SENSITIVITY TO DRUGS

By DR. WALTER KOCH and DR. DEBORAH KAPLAN

Department of Microbiology and Public Health, Chicago Medical School, Chicago, Illinois

THREE methods are in use for testing sensitivity to drugs: (a) the accurate but laborious tube dilution method; (b) a method in which drugs are incorporated into ditch plates; (c) a method in which disks are impregnated with drugs. The last method, for its simplicity, is commonly used in clinical laboratories. In this method, the disk is placed on the surface of a sown, solid medium. The drug diffuses, and the presence of a zone, in which growth is inhibited, and the diameter of this zone, are considered to be indicative of the sensitivity of the organism towards the drug. However, it is difficult to relate the diameter of such a zone to results obtained in tube dilution tests. The diameter of a zone also represents a measure of the diffusibility of the drug. Penicillin, for example, has a much higher diffusibility than polymyxin, for which much higher disk contents are used¹. Another shortcoming of the disk method is that no estimate of combined activity can be given. The zone reading indicates inhibition of organisms by the drug which diffuses through agar most rapidly².

In order to obtain a faster and more uniform diffusion, impregnated paper disks were placed at the bottom of 10-mm × 75-mm test tubes, and 0.5-ml. Baltimore Biological Laboratory soy agar was poured on them. Hereby the path which the drug had to travel was kept extremely short. After 1 h the agar was inoculated with 0.05 ml. of an 18-h-old culture of *Staphylococcus aureus*, type 81, standardized to contain 10⁶ organisms/ml. (ref. 3). The results, however, were not consistent. When pouring the agar over the disk, a slightly raised agar rim forms. This rim apparently contains less drug than the plane surface of the agar. Colonies often developed on the rim, while growth was absent from the plane part of the agar.

Further experiments were carried out with streptomycin disks, containing 2, 5 and 10 µg, cut into halves and quarters. It was found that the degree of elution depends on the size of the exposed area. For example, one half of a 2 µg disk did not inhibit growth, while another half, cut into two quarters, did inhibit growth; one-half of a 5 µg disk did not inhibit growth, while growth was inhibited by a whole 2 µg disk.

We then went over to flat-bottomed, cylindrical 'Lucite' cups, which could stand in a closed Petri dish. Their

inner height was 8 mm, and their inner diameter 7 mm. Drugs were dissolved in distilled water, and the same volume of different drug concentrations dispensed into these cups. The cups were then dried *in vacuo* over 'Drierite', and stored in the refrigerator. Into the dried cups 0.3 ml. agar was dispensed and, after 1 h, they were inoculated.

Parallel experiments were carried out in tubes containing 10 ml. broth. Agreement was good for streptomycin. Whenever in the 10-ml. broth tubes growth was slight, in agar cups, at similar concentrations of streptomycin only a few colonies appeared on the surface.

Unexplained inconsistencies occurred with penicillin. We suspected a loss of penicillin while drying. In order to avoid this loss, different substances were added to penicillin before drying. The following substances proved not to interfere with penicillin activity: glycerol, egg albumen, and nutrient broth. Despite these additions, the differences in apparent penicillin resistance between reconstituted cups and 10-ml. broth tubes remained.

At this time it was found that, in tube dilution tests, using 10 ml. total volume of broth, inoculum size influences the results in penicillin-resistant strains⁴. In order to test whether size of inoculum is the only cause of the discrepancies, the dried penicillin was reconstituted not in agar but in 0.2 ml. nutrient broth, which already contained the inoculum. It was confirmed that inoculum size also influences the results in 0.2 ml. total volume of broth. However, results were not the same when tests were carried out in different broth volumes with the same size of inoculum.

Tests were carried out in which inoculum size (10³, 10⁴, 10⁵ and 10⁶) as well as total broth volume (0.2, 1, 2.5, 5 and 10 ml.) were varied. The following resistant strains were tested for penicillin sensitivity: *Staphylococcus*

Table 1. MEAN INHIBITION DOSES OF PENICILLIN PER ML. FOR DIFFERENT INOCULUM SIZES AND FOR DIFFERENT TOTAL VOLUMES OF BROTH

Total volume of broth (ml.)	Strain 81			
	10 ³	Total inoculum 10 ⁴	10 ⁵	10 ⁶
0.2	1.13	3.75	100	1,250
1.0	1.33	2.17	68	1,166
2.5	1.90	3.07	21	300
5.0	1.70	2.20	9	110
10.0	1.20	1.37	4	50

Table 2. THE THREE RECOMMENDED DOSES PER ML. FOR PENICILLIN (A), (B), (C), STREPTOMYCIN (E), (F), (G), AND COMBINATIONS THEREOF (J), (K), (L) Inhibiting dose of penicillin (D) and streptomycin (H). Total inoculum: 10^8 . Total volume of broth: 0.2 ml. Plus sign indicates growth; minus sign absence of growth. Penicillin in units, streptomycin in μ g

Strain	Penicillin				(E) 2	Streptomycin		(H)	Penicillin + streptomycin		
	(A) 1	(B) 3.16	(C) 10	(D)		(F) 6.32	(G) 20		(J) 1+2	(K) 3.16+6.32	(L) 10+20
80	+	+	+	113	+	+	+	913	+	+	+
81	+	+	+	108	+	+	+	8.1	+	+	+
MG	+	+	+	47	+	+	+	175	+	+	+
45162	+	+	+	100	+	+	+	750	+	+	+
46422	+	+	+	23	+	+	+	6,125	+	+	+
65126	+	+	+	100	+	+	+	542	+	+	+

aureus 80, 81, MG: and three 'Oxford' strains: 45162, 46422 and 65126. As all these strains gave similar results, 81 is chosen to represent the group. Results are summarized in Table 1; figures listed are averages of at least five experiments.

From Table 1 it can be seen that the volume of broth does not play a relevant part with small (10^3 and 10^4) inocula; with larger (10^5 and 10^6) inocula, results become dependent on total volume of broth. By choosing an inoculum of 10^5 micro-organisms for a total volume of 0.2-ml. broth, the results, in all instances tested, are rendered comparable to those obtained in 10-ml. broth in the tube dilution method.

In contrast to the foregoing, penicillin-sensitive strains tested (*Staphylococcus epidermidis*, *aureus*, 52A, 79, and three 'Oxford' strains: 46407, 46426 and 46479) show little dependence on broth volume.

The single 'Lucite' cups were now replaced by a plastic slab, which fits into a Petri dish. Twenty-five cavities were drilled into the slab. Eight radii of three cavities each radiate from a central cavity, which serves as control (Figs. 1a and b).

Into these cavities 0.05-ml. drug solutions were dried *in vacuo* over 'Drierite'. Different drugs, in different concentrations, singly or in combination, with or without glycerol, were dried into the cavities. Glycerol, in a concentration of 0.5 per cent of the fluid to be dried, facilitates reconstitution, and imparts to the dried drugs in the cavities a glossy sheen.

The dried slabs were tested immediately after drying, and after varying storage times; after two months' storage the same results were obtained.

Fig. 1. a, Plan of slab. Twenty-four cavities are arranged in 8 radii. Each radius is formed by three cavities. The cavity in the centre accommodates the growth control. The small circles within each cavity are filled in, where growth occurs. b, Slab in Petri dish, cut through cavity 7 to cavity 19. Growth settles in the tip of the cavity

Slabs with dried drugs were subjected to shaking for 2 h in an inverted position; no loss in potency was observed.

For practical purposes, only three concentrations of a drug, or combinations of drugs, are needed to arrive at a valid estimate. The three concentrations are accommodated in the three cavities of a radius. One cavity contains the maximum attainable concentration of the drug in the blood; penicillin, for example, 10 units/ml. The third cavity contains one-tenth of this concentration; penicillin, for example, 1 unit/ml. The intermediate cavity of the radius contains the geometric mean, namely: $\sqrt{10 \times 1} = 3.16$ units/ml.

An organism which grows in the presence of the highest concentration of the drug is considered resistant. An organism which grows in the presence of the intermediate concentration is considered moderately sensitive. An organism which grows in the presence of the lowest concentration only is considered sensitive. If no growth occurs at any concentration the organism is considered highly sensitive.

For combinations of drugs also, the highest concentrations are the maximum levels attainable in blood; for example, penicillin 10 units/ml. plus streptomycin 20 μ g/ml. The lowest concentrations of drugs are one-tenth of the highest; penicillin 1 unit/ml. plus streptomycin 2 μ g/ml. The intermediate concentrations are the geometric means: penicillin 3.16 units/ml. plus streptomycin 6.32 μ g/ml. The interpretation of results is the same as for single drugs.

Table 2 illustrates results obtained from several strains.

From Table 2 it can be seen that *Staphylococcus* type 81 is penicillin-resistant (inhibitive dose 108 units/ml.), and moderately sensitive to streptomycin (inhibitive dose 8.1 μ g/ml.). This organism, however, is sensitive to a combination of penicillin and streptomycin (inhibitive doses: penicillin 2 units/ml. plus streptomycin 4 μ g/ml.). *Staphylococcus* 46422 is penicillin-resistant (inhibitive dose 22.5 units/ml.), streptomycin highly resistant (6,125 μ g/ml.), and is moderately sensitive to the combination of both (inhibitive doses: penicillin 10 units/ml. plus streptomycin 20 μ g/ml.).

On the other hand, *Staphylococcus* 65126, which is penicillin-resistant (inhibitive dose 100 units/ml.), and streptomycin-resistant (inhibitive dose 542 μ g/ml.), remains resistant to the combination of both drugs.

In the proposed method all one has to do with the prepared slab is to adjust an 18-h-old culture of micro-organisms in broth so as to contain 5×10^5 bacteria/ml., and to dispense 0.2 ml. into each cavity, starting with the cavity in the centre, the control. Results are clearly read with the naked eye; even the slightest growth can be detected. A sediment mostly forms in the tip of the cavity. Results are comparable with those from the tube dilution method in 10 ml. An estimate of combined drug activity is obtained.

We thank Dr. R. L. Vollum, director, Bacteriology Laboratory, Radcliffe Infirmary, Oxford, for kindly sending us the strains.

Sargassum TANNIN, AN ANTIBIOTIC WHICH RETARDS FOULING

By PROF. JOHN McN. SIEBURTH and PROF. JOHN T. CONOVER

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island

THE pelagic gulfweeds, *Sargassum natans* and *S. fluitans*, which belong to the Phaeophyta, have branch tips which are virtually free of an epibiota when they are at the centre of their distribution in the Sargasso Sea gyre. These tissues possess antibacterial activity¹. During filter-pad antibacterial assays the colour of active young tissues turned from yellow-green to black on incubation, while older and inactive preparations remained brownish in colour. This observation brought to mind the black pigment phycophaein formed by the oxidation of phaeophyte tannins² and the use of *Sargassum ring-goldianum* extracts in the tanning industry³. Extracts of actively growing branch tips were astringent, precipitated gelatin, and blackened ferric chloride solutions. These properties are characteristic of tannins, further suggesting that tannins were present in appreciable quantities in these tissues. Further observations were made during R.V. *Trident* cruise 10 (September 7-20, 1963) to the Sargasso Sea.

From samples of fouled weed a sensitive *Pseudomonas* strain was isolated and used as a test organism. This organism was more sensitive and had a shorter incubation period than the *Vibrio* isolate used previously¹. Only in material south-east of Bermuda in the Sargasso Sea gyre was there marked antibacterial activity and the presence of tannin-like substances in the branch tips. A comparison was made of the antibacterial activity of tannic acid (U.S.P., 'Mallinckrodt') and that of *S. natans* extracts (Fig. 1). Inhibition by tannic acid was detectable at concentrations greater than 0.01 per cent and was linear above 0.1 per cent. The more active *S. natans* preparations showed inhibition equal to that of a 0.2 per cent tannic acid solution. Although the inhibitory tannic acid and algal extracts were acidic, a hydrochloric acid solution diluted to pH 3.85 failed to inhibit the test organism. Inhibition by tannic acid and the phaeophyte tannin may be due to their protein precipitating activity.

Since tannins by definition precipitate protein, an attempt was made to observe the effect of adding extracts of young branch tips to the epifauna of fouled weeds. Hydroids (such as *Plumaria* and *Olytia*) were ideal test organisms as their tentacles remained active even after being poked by a glass rod or being hit by drops of sea-water. Initial observations with drops of a 1:4 w/v suspension in 25 ml. of sea-water 'froze' the active tentacles, which became deformed and exuded strings of

precipitated protein. The results with hydroids were so marked that a series of observations with different dilutions were made on a number of members of the epifauna; the results are summarized in Table 1. Dilutions of 1:125 affected most of the fouling organisms, while the hydroids were sensitive to dilutions as great as 1:1,000. Tannic acid solutions had a similar spectrum of activity with 0.0008 per cent solutions immobilizing 50 per cent of the hydroids. The tissue content of the 'tannins' appears to be sufficiently high to retard fouling.

Several attempts were made to concentrate and purify the 'tannins'. Only young branch tips free of fouling were suitable. Extraction was made difficult by the marked decrease in antibacterial activity following collection. Even when the tissue was preserved by freezing in packed plastic bags the activity was minimal after two to three weeks. The most successful extraction was conducted aboard ship on fresh material. Young branch tips triturated in a Waring blender with sufficient distilled water to make a slurry were extracted at 50° C for 15 min, and coarse-filtered through a clean towel to yield an opalescent suspension. Most of the chlorophyll was removed by repeated ether extraction. A red-brown fraction was brought into an iso-amyl alcohol phase with sodium sulphate. The iso-amyl alcohol fraction was evaporated to dryness in a rotary evaporator, and the residue was extracted with acetone. The acetone-soluble fraction was also evaporated to dryness, and the residue was taken up in a minimal amount of water to yield a deep amber-coloured liquid. This procedure extracted half the antibacterial activity as shown by assays while reducing the volume a hundred-fold. The dried extract had the solubility characteristics of *Sargassum* tannin², darkened a ferric chloride solution, precipitated gelatine, and was highly astringent. The insolubility of the active material in ethyl ether separates this material from the ether-extractable antibacterial, sarganin, reported for *S. natans*⁴.

The presence of tannic substances in brown algae is associated with refractile, acidic vesicles called physodes, fucosan vesicles or metachromatin granules^{2,5}. The excretion of phenolic substances from the physodes of living algae has been recently reported⁶. Accumulation of these tannins was greatest in the distal tips of the thalli. Antibacterial activity in extracts of epibiont-free branch tips of *S. natans* from the Sargasso Sea was observed in early October 1962 and September 1963 (R.V. *Trident* cruises 1 and 10), as well as in week-old frozen material brought back from other summer and autumn cruises. In contrast, observations made in January 1964 (R.V. *Trident* cruise 14) indicated that even the branch tips were fouled by

Fig. 1. Comparison of antibacterial activity and pH of tannic acid solutions with those obtained from young and old tissue suspensions (1:4 w/v) of *Sargassum natans*. A hydrochloric acid control of pH 3.85 did not inhibit the pseudomonad test organism.

hydroids and that antibacterial activity was not detectable. Both dried and preserved specimens were examined critically for physodes, which occur as yellow-refractive spherules 1 μ in diameter. The active distal tissue of algae collected during cruise 10 possessed 40–68 physodes per cell in contrast to 2–12 physodes from similar but inactive tissues from cruise 14. The presence of physodes appears to be coupled with antifouling in brown algae. This is further substantiated by reports on the absence of physodes in the cells of host brown algae adjacent to the invading filaments of parasitic epiphytes⁷. The antibiotic activity of marine algae in temperate zones has been shown to vary seasonally, peaks in activity occurring during active growth and being dependent on the boreal or tropical nature of the plant⁸. A drop of 3° C in the temperature of surface waters between cruises 10 and 14 was apparently sufficient to alter the physiology and antifouling activities of these plants. These observations on the seasonal change in the number of physodes per cell, in addition to those on tannin activity and antifouling in branch tips, further indicate the excretory function of these vesicles.

The recent work of Craigie and McLachlan⁹ has shown that a number of phaeophycean algae produce yellow, ultra-violet-absorbing materials which appear to be flavonols or catechin-type tannins. These substances were found to be toxic to unicellular algae at concentrations of 0.025–0.15 per cent. Concentrations of natural tannins similar to those inhibitory for our pseudomonad were also inhibitory for cellulolytic but not saprophytic bacteria⁹. The phaeophyte tannins should be included among the known algal antimicrobials¹⁰.

These observations indicated that tissues of algae containing tannins equal in activity to 0.1–0.8 per cent tannic acid (dry weight) retard fouling in *S. natans* and that unprotected tissues such as the tentacles of hydroids are sensitive to tannic acid solutions as dilute as 0.0008 per cent. Since fouling is one of the outstanding economic problems facing marine biology, an attempt was made to see if tannic acid *in vitro* would also retard fouling. Tannic acid (U.S.P., 'Mallinckrodt') dissolved in acetone at a 15 per cent (w/v) concentration. This solution was added to varnish and lacquers in equal volumes. Control preparations were diluted with acetone alone. Similar

preparations were made with paints using the cheaper grade of 'fluffy' tannic acid (N.F., 'Mallinckrodt'), but these were prone to peeling. Test panels were immersed both in Narragansett Bay, Rhode Island, and in Biscayne Bay, Florida. Although the tannic acid preparations were inferior to commercial antifouling paints, they did inhibit fouling by both barnacles and algae under both temperate and tropical conditions.

The antifouling properties of tannins were claimed as early as 1881 and paints containing tanner's bark, poke-root bark, pine bark, kelp and mangrove tree extracts have been granted U.S. Letters Patents as antifouling compositions of matter¹¹. Although tannins may be effective inhibitors to bacterial, algal and animal fouling organisms in young and actively growing tissues of at least the brown algae, their economic application is undoubtedly limited.

I thank colleagues and students, S. P. Meyers, Institute of Marine Science, Miami, Florida, and James H. Ware, International Minerals and Chemical Corporation, Skokie, Illinois, for their assistance. This work was supported in part by a grant from the U.S. Public Health Service (WP-00100-02) and a contract with the U.S. Office of Naval Research (Ncr 396-08).

Note added in proof. Subsequent investigations have shown that tannins from *Ralfsia verrucosa* affect the survival of planktonic animals in tide-pools (*Proc. Fifth Intern. Seaweed Symp.*, Halifax, August 1965).

COMPARISON OF THE CHORIOALLANTOIC MEMBRANE AND SPLENO-MEGALY SYSTEMS OF GRAFT-VERSUS-HOST ASSAY IN THE CHICK EMBRYO

By L. W. COPPLESON* and DR. DONALD MICHIE†

Medical Research Council, Research Group on Clinical and Experimental Problems of Transplantation, Department of Surgical Science, University of Edinburgh

THE chick embryo can be used as the arena of graft-versus-host reactions in two ways that are convenient to measure. Intravenous injection of immunologically competent cells results in an enlarged spleen which may be weighed¹. If a suspension of adult chick leucocytes is placed on the dropped chorioallantoic membrane (CAM) of a developing chick embryo, small white foci appear which may be counted²⁻⁴. This article describes the biometrical properties of the two systems as assays of immunological activity, and compares their efficiencies. The materials and methods used have been described elsewhere^{5,6}.

Assay systems

The essential feature of an assay is the expression of the concentration of some biologically active principle in a test preparation in terms of a standard preparation.

* Present address: McIndoe Memorial Research Unit, Blond Laboratories, Queen Victoria Hospital, East Grinstead, Sussex.

† Present address: Experimental Programming Unit, University of Edinburgh.

Estimates obtained therefore take the form of a relative potency. In illustration, we present a single assay more fully, in which the CAM reaction was used.

The material to be assayed consisted of frozen adult chick buffy coat cells⁶. The cell concentration of the test suspension was 4/3 times greater than that of the standard (unfrozen) suspension in order that the same part of the dose-response curve should be used as nearly as possible. The test cells, suspended in a solution containing 15 per cent dimethylsulphoxide and 30 per cent chick plasma, were frozen to -195° C and kept there for 0.5 h. The standard and test were each applied at three dose-levels, 1 in 1, 1 in 3 and 1 in 9; making 6 batches (that is, a 6-point assay⁷). A seventh batch of saline-treated eggs was included as a check for non-specific lesions, which occurred sufficiently rarely to be ignored. Six eggs were assigned to each batch.

The estimation of relative potency (relative immunological reactivity per cell) is illustrated in Fig. 1, using data from the first week of a series of seven replicates.

Fig 1 Illustrative assay of the immunological potency of a suspension of adult chick leucocytes using the CAM reaction. Serial three-fold dilutions were used, all doses are expressed as log cell concentration. The response is expressed as $\log(\text{No. of foci} + \frac{1}{2})$. ●, Standard; ○, test

The two parallel lines are the calculated lines of best fit, and the relative potency can be read off by taking the antilog of 0.544 which is 3.5 approximately, that is, the standard preparation has 3.5 times the potency of the test. Actually it is conventional to express the test in terms of the standard, so that we would say that the relative potency is $1.0/3.5$, that is, 0.29.

Parameters of the CAM system

Choice of interval. Inoculations were made on day 12 to conform with the practice of the Burnet group^{2,3,8}. Day 13 was tried but produced no appreciable difference from day 12. The membranes were collected 4 days after inoculation. Examination of day 5 and isolated trials of longer periods revealed such problems in the identification and counting of individual foci that the counts were considered less reliable than those obtained with a 4-day interval.

Numerical expression of response. In the CAM response, as has been shown elsewhere⁵, the scatter around the mean is grossly dependent on the mean itself, and hence on dose-level. Logarithmic transformation was found adequately to correct this feature. Since the counts occasionally contained zero values and the logarithm of zero is an infinite negative quantity, the transformation used was $\log_{10}(\text{No. of foci} + \frac{1}{2})$ rather than $\log_{10}(\text{No. of foci})$.

Parameters of the splenomegaly system

Choice of interval. Day 13 was chosen for intravenous injections as being technically extremely convenient and also because Solomon and Tucker's results⁹ indicate that maximum reactivity is developed at about this stage. Intervals of 3, 4 and 5 days were tested in two batches of Stirling eggs and one of inbred eggs (C-Line, Poultry Research Centre, Edinburgh). Using as the criterion of efficiency the ratio of the observed spleen enlargement to its standard deviation, the indicated order of preference in each case was 4 days, 5 days, 3 days. Four days was chosen as the interval for all subsequent work.

Numerical expression of response. The classical index of splenomegaly used by Simonsen was the ratio of the spleen weight in treated animals (mice) to that in litter-mate controls. In more recent work it has been customary to work with the logarithm of this ratio. In the chick the need for controlling inter-litter variation does not arise, so that the single measure $\log_{10}(\text{spleen weight})$ has been used throughout. Before standardizing on this measure one other possibility was investigated, namely, $\log_{10}(\text{spleen weight of treated embryos} - \text{mean spleen weight$

of untreated embryos). The expression inside the brackets measures the extra tissue present in the organ as a consequence of treatment. This transformation, while resulting in an improved slope, caused a deterioration in variance sufficient to counterbalance the gain.

Comparison of the CAM and splenomegaly systems

It was first pointed out by Gaddum¹⁰ that an objective measure of the efficiency of an assay system can be calculated from the dose-response slope, b , and the within-batch standard deviation, s . The quantity s/b is usually regarded as a convenient inverse measure of efficiency, having the property that its square, s^2/b^2 , is directly proportional to the number of animals which need to be used to attain a given precision in the estimate of relative potency¹¹. In an examination of 45 parallel-line assays for various drugs, Bliss and Cattell¹² found values of s/b ranging from 0.03 to 0.50.

Table 1. RELATIVE EFFICIENCY OF CAM AND SPLEEN ASSAYS IN STIRLING (S) AND $RIR \times LS$ MATERIAL

Stirling (S)		$RIR \times LS$	
CAM assays*	Spleen assays*	CAM assays†	Spleen assays

Figures represent the mean of s/b which is an inverse measure of the efficiency of the assay. Figures in parentheses denote the number of replicate assays performed.

* Includes data from ref. 6.

† From ref. 5.

In Table 1 we have set out some measures of efficiency obtained from 29 separate assays. It appears that in the Stirling embryos the splenomegaly system is more efficient whereas in the $RIR \times LS$ cross-breds the CAM system is more efficient. This interaction between genotype and test system is a real effect. If we compare the $S - (RIR \times LS)$ difference on the CAM test with that obtained on the splenomegaly test, the difference is significant at the 1 per cent level.

On the grounds of efficiency alone there is thus little to choose between the two methods of assay, the most important consideration being to fit the choice of recipient material to the assay system. Given suitable strain combinations, the choice between the two systems becomes primarily a matter of technical convenience. In the spleen assay it takes longer to administer the doses, but the response is less tedious and more objective to read. Therefore, for simple relative potency estimations the splenomegaly system is to be preferred. In the CAM system, on the other hand, inoculations are quick and easy, but the response is laborious and difficult to read. Consequently, the circumstances under which the CAM system is likely to be preferred are those in which it is desired to take advantage of the 'one focus, one competent cell' relation postulated by Burnet and supported by our own investigations⁶.

FINE STRUCTURE OF WOOD

By DR. P. RUDMAN*

Leverhulme Visiting Fellow, Astbury Department of Biophysics, University of Leeds

ALTHOUGH the advent of electron microscopy, and in particular the replica and shadowing techniques, has revealed the microfibrillar orientation in the lamellae of the primary wall (P) and the secondary wall layers (S_1 , S_2 and S_3), it has contributed little to our knowledge of cell wall capillaries or of intermicrofibrillar spaces. For general physiological reasons it is believed that cell wall capillaries exist; but until recently this belief was based on indirect evidence such as the weight/weight uptake of liquids by wood, or the encrustation of tracheid fragments with iodine¹ and the X-ray scattering of untreated and gold impregnated wood before and after delignification². More recently it was shown that electron diffraction diagrams of *Pseudotsuga menziesii* treated with inorganic solutions were consistent with cell wall penetration; the walls stained with dithio-oxamide throughout (but patchily), the middle lamella being heavily stained³⁻⁶. It was noted that the resulting complex was dichroic and similar dichroism has been found by other workers using different inorganic solutions in other softwood species^{7,8}. Such findings have been taken to indicate³⁻⁶ that the complexes are oriented parallel to the microfibrils of the cellulose fraction in these walls.

It has been found by Wardrop and Davies⁹ that when *Pinus radiata* is stained with congo red the layers S_1 and S_2 stain strongly, whereas the S_3 stained less strongly with the middle lamella barely staining. The authors suggested that if it were accepted that the degree of staining was indicative of the presence of capillaries of a particular minimum size, the observation would indicate that the capillaries in the true middle lamella were smaller than those of other regions; furthermore, the number of capillaries into which the dye could penetrate was greater in the layers S_1 and S_3 than in the layer S_2 . Optical microscopy and low-magnification electron microscopy have shown that copper-treated *P. radiata* contains tracheids in which the copper is in or is external to the layer S_1 (ref. 9); no fine structure was revealed in this work. Mention must be made of the pioneering work of Stamm¹⁰, whose investigations on flow demonstrated the existence of pores in the cell walls of wood cells. Similar work¹¹ based on electrical conductivity has recently confirmed that pores other than those in the pit membrane must traverse the cell wall completely.

Only one electron micrograph has been published^{5,6} which illustrates that a cell wall capillary may be filled or partly filled with an inorganic salt; in this micrograph, a few isodiametric deposits of a copper-chrome-arsenic wood-preserved may be seen in the cell wall of a tracheid of *P. menziesii*.

Other plant fibres are known to contain intermicrofibrillar spaces; but again it cannot be said that these are true capillaries because of the techniques adopted to reveal them. Wardrop⁹ has shown that in sections of fragments of delignified flax fibres treated with gold chloride solutions it was possible to see an irregular deposition of the salt. It was assumed that surface crystallization had commenced and that aggregates had formed in the 'grooves' between adjacent microfibrils. More recently, macerated ramie fibres treated with inorganic salts solutions have yielded excellent electron micro-

graphs showing oriented deposition of metal in the cell wall¹².

A study of the cell wall capillaries and pit membranes in wood has now been undertaken because of its wider implications in the field of wood-preservation. It was assumed that interstices could occur between and parallel to the microfibril, and that interstices in adjacent lamella would sometimes be linked, probably randomly, so that in effect a capillary system across and along the cell walls could exist. In theory it was thought that such a capillary system would allow the passage of polar liquids (but probably not non-polar liquids) from cell lumen to middle lamella, and, if this were also permeable, to the cell wall of the adjacent cell. Cutting of ultra-thin sections parallel to the microfibrillar orientation in metal-containing wood should then reveal the capillaries as elongated electron-dense zones, with more isodiametric zones indicating interstices linking lamellae.

Sapwood samples (3 in. long. \times 1 in. tang. \times 1 in. rad.) from two species of the hardwood genus *Eucalyptus* were placed under vacuum to remove air and then pressure-treated at 70 lb./in.² with aqueous solutions, either 10 per cent aqueous silver nitrate followed by 10 per cent aqueous hydrazine hydrate, or with a 10 per cent aqueous copper-chrome-arsenic wood-preserved ('Tanalith C'). After air drying, thick sections (30 μ) were cut at a small angle to the cell axis and portions of these embedded in methacrylate, 'Araldite' or 'Epon'. Thin sections (500 Å) were cut and examined in the electron microscope. Fig. 1 illustrates silver deposition in the capillaries in the S_2 and S_3 layers of a fibre tracheid from *E. obliqua* sapwood sections cut approximately tangentially to the S_2 microfibrillar direction. From this and similar electron micrographs it has been found that the average diameter of the deposits, and therefore approximately of the capillaries, is about 300–350 Å, no corrections being made for deformation due to crystal expansion during its growth. This same electron micrograph also shows limited evidence of the orientation in the S_3 layer.

The appearance of the tracheid wall of *E. maculata* sapwood impregnated with 'Tanalith C' (Fig. 2) and silver (Fig. 3) is somewhat different. Here, capillaries appear much smaller (approx. 100 Å) though, again, they can be seen to be oriented in relation to the microfibrils, but only certain areas are readily penetrated by the aqueous solutions. In Figs. 1, 2 and 3 small isodiametric electron-dense zones are also to be seen, indicating capillaries connecting adjacent lamellae.

Because of the importance of pits in any examination of liquid flow in wood, the structure of these has also been investigated. No evidence of large pit membrane pores has been found in *E. obliqua* and *E. maculata*; but the membranes exhibit a random pattern of interstices filled with the appropriate inorganic constituent (Fig. 4). In a few instances the pit membranes have been found to be torn (presumably during the initial sectioning) so that two thin membranes appear to be present. These findings are consistent with the belief that the membrane is composed of two primary walls without lignification and without a middle lamella.

No evidence has been found to indicate that the middle lamella is preferentially penetrated such as has been found previously^{5,9} with softwoods. However, other workers⁸ found that no copper was present in the middle lamella when sections of *P. radiata* were cut from copper-

treated blocks, but could be detected if sections were soaked in copper solutions.

Electron microscopy carried out in the work recorded here has revealed that after pressure impregnation with inorganic solutions the cell lumina are lined with inorganic salts, and it is usual to find that the S_3 layer has been

penetrated fairly frequently. An examination of the figures will show that the S_3 layer is quite an open network, with large capillaries. The rest of the wall is much less frequently penetrated and this could be due, for example, to hydrophobic cytoplasmic debris blocking the capillaries in the S_3 layer. The rather unusual silver deposition in a parenchyma cell of *E. maculata* which is shown in Fig. 5 provides an interesting illustration of relative penetrabilities of the various cell wall layers. It will be seen that, once the initial barrier is penetrated, movement through capillaries occurs and liquids may cross the middle lamella. Significantly, and in general agreement with the findings based on indirect staining investigations⁸, many of the capillaries in the middle lamella are smaller than those in other regions of the cell wall.

This work has illustrated that the cell walls in eucalyptus contain fine capillaries up to 450 Å in diameter, that these may be traversed by aqueous solutions which gain access from the cell lumen, that the middle lamella offers no resistance to flow and that direct access to the middle lamella from the pit chamber (Fig. 4) is not possible. Though the pit membrane contains no large pores, aqueous solutions can pass through it.

When this work is more fully reported elsewhere and the practical implications for the wood-preserving industry discussed, photomicrographic evidence will be presented to illustrate that the pits in eucalypts form the major pathway by which aqueous solutions travel from cell to cell, with the cell wall capillaries serving mainly to distribute the solution to the walls.

A NEW CHEMICAL ASPECT OF PENICILLIN ALLERGY: THE DIRECT REACTION OF PENICILLIN WITH ϵ -AMINO-GROUPS

By DR. C. H. SCHNEIDER and DR. A. L. DE WECK

Allergy Research Unit, Department of Dermatology, University of Berne, Inselspital, Berne, Switzerland

IT seems well established that the penicilloyl group bound to carrier protein structures *in vivo* is a main antigenic determinant in penicillin allergy¹⁻³. On the other hand, the chemical basis for the formation of these penicilloyl protein conjugates has not yet been satisfactorily elucidated. Earlier views on the formation of the penicilloyl haptenic structure have held that a highly reactive degradation product of penicillin, penicillenic acid, might be the only form in which penicillin reacts irreversibly with proteins. Penicillenic acid is, in fact, spontaneously formed from penicillin in neutral solution and is able to react with free amino-groups, thereby forming a penicilloyl-amide⁴. The possibility that penicillins could react directly with ϵ -amino-groups by an opening of the β -lactam ring has been neglected mainly because an experimental demonstration of the reaction between penicillins and such amino-groups on proteins, peptides or low molecular weight amines in neutral aqueous solution was lacking⁵.

Two facts have been known for some time to throw some doubt on the concept of penicillenic acid being a main intermediate in the formation of the penicilloyl haptenic structure: (a) There is no correlation between the *in vitro* rate of formation of penicillenic acid from various penicillins bearing different acyl side-chains and the immunogenicity of these penicillins; (b) 6-aminopenicillanic acid (6-APA), being structurally incapable of rearrangement to a penicillenic acid intermediate, was shown to be a strong inducer of the allergic state in rabbits⁶.

In experiments initiated by these considerations, the incubation of penicillins with amines in neutral aqueous solution was examined. It was established that penicillins do react with amines under such conditions to yield penicilloyl-amides. In this article we report in a preliminary form some of our results together with findings obtained with dinitrophenyl-6-aminopenicillanic acid, demonstrating that the direct reaction of the β -lactam of penicillins with amines is an important general route to the penicilloyl-amide antigenic determinant. (A full account of this work will be published in *Helv. Chim. Acta.*)

Benzylpenicillin (0.5 M) was incubated at 37° with ϵ -aminocaproic acid (molar ratio, 1 : 4.25) in 0.5 M phosphate buffer pH 7.4, and also in 0.1 M sodium bicarbonate at pH 7.4. Additions of small amounts of sodium hydroxide kept the pH at the desired value. After one day a viscous gum was precipitated from the reaction mixture by acidification. From the precipitate, crystalline benzylpenicilloyl- ϵ -aminocaproic acid (I) in the form of its dibenzylammonium salt was obtained. The products obtained in the two runs agreed in properties (m.p. 110°–113° and 111.5°–113°. Corrected capillary melting points are reported; $[\alpha]_D^{25} = +69.7^\circ$ and $+69.2^\circ$ ($c=1$, water); penamaldade assay⁷: $E_m = 24,000$) with an

authentic sample of benzylpenicilloyl- ϵ -aminocaproic acid dibenzylammonium salt prepared in alkaline solution. Mixed melting points were not depressed. The yields were 20–30 per cent. In addition, benzylpenicillin was similarly incubated at physiological pH with poly-L-lysine of mean molecular weight about 1,000, the molar ratio of penicillin to ϵ -amino-groups being 1 : 0.4. Passage of the incubation mixture through a 'Sephadex G-25' column neatly separated the polylysine material (peak I) from the residual material (peaks II and III) (Fig. 1). Penicilloyl groups attached to the polylysine were measured by a modified penamaldade assay⁷. In accordance with the behaviour expected for a benzylpenicilloyl polylysine⁷, the material from the column (peak I) specifically precipitated antisera from rabbits which had been immunized with benzylpenicilloyl-bovine γ -globulin.

Other penicillins were incubated for 4 h at 37° with polylysine in 0.05 M phosphate buffer pH 7.4 at a concentration of 75 mM, the molar ratio of penicillin to ϵ -amino-groups being 1 : 1. Polylysine material was isolated from the incubation mixture through 'Sephadex G-25' gel-filtration and the amount of penicilloyl-amide on the polylysine was established by penamaldade analysis. That no other material developing under the conditions of the incubation and detectable by penamaldade assay, was carried with the polylysine peak, was verified in each case by a run in which polylysine was added only at the end of the incubation period. The polylysine peaks

Fig. 1. Gel-filtration of 1 ml. of a solution of benzylpenicillin (250 mg) and polylysine (40 mg) in 4.0 ml. of McIlvaine's citrate-phosphate buffer incubated for 24 h at 37°, pH 7.4. The column (1.8 cm \times 30 cm) containing 'Sephadex G-25' was equilibrated and eluted with McIlvaine's citrate-phosphate buffer. Analysis of eluate: \circ , penamaldade assay (P.A.) as increase in optical density at 282 m μ after HgCl₂ treatment; \blacktriangle , optical density at 257 m μ ; ---, Folin-Lowry colour (ref. 8) as optical density at 750 m μ . Optical measurements were made in 1 cm cells

Table 1. AMINOLYSIS OF PENICILLINS AND DEGRADATION TO PENICILLINIC ACID

Penicillins	Penicilloyl groups on polylysine after incubation of 300 μ moles of penicillins with excess polylysine for 4 h at pH 7.4, at 37° μ moles*	Degradation to penicillenic acid at 37°, from (ref. 6)	
		Mole parts per thousand per min at pH 4.0	Mole parts per thousand per h at pH 7.4

* Calculated from the penamaldate assay with a mean molar extinction of 24,000.

obtained in these control runs did not contain significant amounts of material detectable by penamaldate analysis. The results are shown in Table 1.

These experiments demonstrate the formation of the penicilloyl-amide bond in aqueous solutions at physiological pH. They make it unlikely that the route to penicilloyl-amides proceeds in general through penicillenic acid as a main intermediate, since no correlation between conversion to penicillenic acid of the various penicillins and the formation of penicilloyl polylysine is found (Table 1).

However, the use of a penicillin-like molecule unable to undergo the penicillenic acid rearrangement, but capable of acylating amines in neutral aqueous solution and of inducing the formation of specific antibodies *in vivo*, is required in order to demonstrate unambiguously that the direct acylation of amino-groups by the penicillin molecule through opening of the β -lactam ring, without involvement of a penicillenic acid type intermediate, occurs and constitutes an important route *in vivo* to the penicilloyl-amide antigenic determinant. 6-APA would seem to be a good choice in this respect. However, this compound is peculiar as it reacts easily with carbon dioxide, thereby yielding 8-hydroxypenicillanic acid⁹⁻¹¹. The reaction probably involves a CO₂-6-APA adduct (II) (ref. 9) as an intermediate which conceivably could react with amines. Furthermore, 6-APA is capable of intermolecular acylation by reaction of the amino-group of one 6-APA molecule with the β -lactam ring of another. On repetition of this process, polymers of 6-APA are formed for which evidence has been reported^{12,13}. Since the dimer penicillanyl-aminopenicillanic acid as well as the higher polymers are, in fact, penicillins, they are in principle capable of the penicillenic acid rearrangement. Therefore, the occurrence of a reaction between 6-APA and amines at neutrality could be considered as proof of a direct reaction of the β -lactam with amines only if the reaction products were identified as penicillanyl amides, or if additional information indicated that the contribution of the polymerization under the conditions used is negligible. On the other hand, the first step of the 6-APA polymerization, the *N*-acylation of a 6-APA molecule by a second one, obviously cannot proceed via a penicillenic acid intermediate and constitutes a demonstration of the direct attack of an amino-group on the β -lactam. However, the equivalence in this respect of the reacting amino-group of 6-APA and ϵ -amino-groups could not be taken for granted.

We have obtained preliminary evidence that 6-APA reacts with polylysine in neutral aqueous solution in a nitrogen atmosphere free of carbon dioxide to yield a conjugate which specifically precipitated a rabbit anti-benzylpenicilloyl antiserum. The reaction was followed

by penamaldate assay. It seemed diminished in sodium bicarbonate solution. We have further observed that, in the absence of polylysine and carbon dioxide, a considerable increase of material showing a penamaldate assay results on incubation of 6-APA alone in neutral solution. This could be due to hydrolysis but in part also to polymerization of 6-APA.

In view of the complications connected with 6-APA work, we proceeded with dinitrophenyl-6-aminopenicillanic acid (DNP-APA) (III). This substituted 6-APA contains all the features of penicillins required for the demonstration of a direct aminolysis of the β -lactam since a penicillenic acid rearrangement cannot occur and potential side-reactions of 6-APA are avoided by the blocking of the 6-amino-group. The compound was prepared by reacting 6-APA with dinitrofluorobenzene in a mixture of acetone and sodium bicarbonate solution. The DNP-APA could be well crystallized as the free acid from ether and from acetone-water (m.p. 164°. Analysis, calc. for C₁₄H₁₄O₇N₂S: C, 43.98; H, 3.69; N, 14.65; found: C, 44.23; H, 3.90; N, 14.58; neutralization equivalent, calc. 382.3; found: 383).

This compound (2.5 g) was incubated with ϵ -aminocaproic acid (3.8 g) in 0.1 M phosphate buffer (8 ml.) at 37° for one day. The incubation solution was kept at pH 7.2 with the aid of a pH-stat, delivering 1 N sodium hydroxide to the reaction vessel. Dinitrophenyl-6-aminopenicillanyl- ϵ -aminocaproic acid was isolated in the form of its crystalline dibenzylammonium salt in nearly 40 per cent yield (m.p. 135°–137°. Analysis, calc. for C₂₄H₄₅O₉N₇S: C, 56.10; H, 6.23; N, 13.47; found: C, 55.84; H, 6.71; N, 12.93; penamaldate assay: $E_m = 25,000$). Manipulations were performed in subdued light, since the desired product as well as DNP-APA itself are light-sensitive in neutral solution.

The formation of dinitrophenyl-6-aminopenicillanyl- ϵ -aminocaproic acid from DNP-APA and ϵ -aminocaproic acid in 0.05 M phosphate buffer at pH 7.4 was compared to the formation of benzylpenicillanyl- ϵ -aminocaproic acid from benzylpenicillin and ϵ -aminocaproic acid under the same conditions. To this end, solutions (0.36 M) of DNP-APA and benzylpenicillin in 0.05 M phosphate buffer were incubated in a pH-stat at pH 7.4 at 37° alone and in the presence of 1.45 M ϵ -aminocaproic acid. The opening of the β -lactam ring was followed by penamaldate assay¹⁴. Figs. 2 and 3 show the very similar rates of

Fig. 2. Incubation of DNP-APA at pH 7.4, at 37°. ■, Alone; ○, in the presence of ϵ -aminocaproic acid. Penamaldate assay (P.A.) as increase in optical density at 282 m μ after HgCl₂ treatment (1 = 1 cm)

Fig. 3. Incubation of benzylpenicillin at pH 7.4 at 37°. ■, Alone; ○, in the presence of ϵ -aminocaproic acid. Penamaldate assay (P.A.) as increase in optical density at 282 m μ after HgCl₂ treatment (1 = 1 cm)

formation of the dinitrophenyl-6-aminopenicillanyl group and the benzylpenicilloyl group in the presence of ϵ -aminocaproic acid. The rate of hydrolysis of both DNP-APA and benzylpenicillin appears negligible under the conditions used. This result indicates similar rates of aminolysis for DNP-APA and benzylpenicillin and implies that the contribution of the penicillenic acid route to the aminolysis of benzylpenicillin could only be small under the *in vitro* conditions used.

The immunogenicity of DNP-APA was tested in rabbits. Animals were injected with DNP-APA and complete Freund's adjuvant (Difco) according to a procedure described previously¹. Antibodies specific for the dinitrophenyl-6-aminopenicillanyl determinant were demonstrated in the rabbit sera by haemagglutination¹. For the haemagglutination reaction, rabbit antisera absorbed with normal sheep erythrocytes were incubated with sheep erythrocytes previously treated with DNP-APA or benzylpenicillin in 0.1 M veronal buffer at pH 9.0. The haemagglutination titres of anti-DNP-APA sera with DNP-APA treated cells were comparable to those obtained with anti-benzylpenicillin rabbit sera and benzylpenicillin treated cells. The haemagglutination reaction was specifically inhibited by dinitrophenyl-6-aminopenicillanyl- ϵ -aminocaproic acid and by benzylpenicilloyl- ϵ -aminocaproic acid. The former compound was a more effective inhibitor. Only 1×10^{-4} M dinitrophenyl-6-aminopeni-

cillanyl- ϵ -aminocaproic acid was required in order to achieve the same degree of haemagglutination inhibition as obtained with 6×10^{-3} M benzylpenicilloyl- ϵ -aminocaproic acid.

The experiments described here demonstrate the reaction of penicillins with ϵ -amino-groups at physiological pH. It is shown that the resulting penicilloyl-amides are formed by direct penicilloylation without necessarily involving a penicillenic acid intermediate. Even in the case of benzylpenicillin, the contribution of the penicillenic acid route appears small under certain *in vitro* conditions. DNP-APA, which has no possibility of reacting via a penicillenic acid intermediate, was shown to be immunogenic in rabbits. It is therefore suggested that the direct penicilloylation of carrier protein structures is a general route to the penicilloyl antigenic determinant *in vivo*.

While this article was being prepared, the paper by Batchelor, Dewdney and Gazzard¹⁵ came to our notice. It is remarkable that some of the lines of thought were quite similar in the two laboratories.

This work was supported in part by grants of the U.S. Public Health Service, of the Swiss National Foundation for Scientific Research and of the Emil Barrell Foundation.

I thank Mrs. E. Stäuble for assistance.

OSMOTROPOTAXIS IN THE HONEY-BEE

By DR. H. MARTIN

Zoological Institute, University of Frankfurt

OLFACTORY orientation in insects can follow two different paths: (a) Sampling of the scented area with movable antennae in temporal sequence makes it possible to perceive differences in the concentration of the scent and to make adjustments in a klinotactic orientation. This alone can be carried out with a single sensory organ on one side. (b) Simultaneous spatial perception of the scent gradient by both antennae: the animals succeed in orienting themselves tropotactically to the scent source. That two sense organs lie symmetrically on the body must be assumed (theoretically receptor can replace the word sense organ¹).

Many authors believe that osmotropotactic orientation can be shown in one-antenna animals. One-antenna animals move in circles toward the antenna side in a scent current, in a different scent area, and also in a scent gradient, *Geotrupes silvaticus* Panz. and *Geotrupes vernalis* L.², *Calliphora erythrocephala*³, *Leptinotarsa decemlineata* Say⁴, meal-worm beetle⁵, *Drosophila melanogaster*^{6,9},

Habrobracon juglandis Ashmead⁷, *Ips curvidens*⁸, and silkworm¹⁰.

On the other hand, experiments have been performed with one-antenna animals as proof of a klinotactic olfactory orientation. The animals with one antenna still show a fully developed olfactory orientation; sometimes they show only a slight deviation towards the antenna side. Attaining the goal results from klinotaxis, and for this one antenna suffices for *Rhodnius prolixus*¹¹, *Nemeritis canescens*¹² and *Geotrupes silvaticus* Panz¹³.

Other authors discuss olfactory orientation as quite a different mechanism. The scent acts only as a stimulant. Actual finding of the objective is only possible when an air current gives the animal the chance to fly rheotactically against the scent gradient^{6,14-17}.

For the first time we have succeeded in showing osmotropotactic orientation in a scent area for bees^{18,19}. The way it works, its quantitative effect, and its interaction with osmoklinotaxis are described in this article.

Normal and experimental bees trained to a scented food source had to show in an appropriate experimental situation that they were able to distinguish between the scentless and the scent-filled branches of a Y-tube (Figs. 1a and b). At the moment of the decision they had the choice of running into one or the other of the tube branches in order to reach the food. The experimental set-up was free of air currents. The Y-tube was placed at an angle of 5° – 6° to the horizontal plane. This guaranteed a flow of scent molecules (rate of flow: 0.3–1.5 cm/sec). Observation was through a ruby glass plate.

(1) *Bees with one movable antenna and with fixed antennae.* With the scent source on one side (0.002 ml. oil of anise), normal bees run straight to the scented box (Fig. 2). 2.5 sec were required to run a distance of 11.5 cm; 87.0 per cent positive choices were made. If one antenna is cut off the orientation towards the scent is scarcely impaired (78.8 per cent positive runs). Only occasionally a slight 'zig-zagging' can be observed. A tendency to move sideways^{5,9,10} does not occur: time per run, 2.9 sec. If both antennae were fixed in their normal position

Fig. 1. a, Experimental arrangement for the Y-tube tests; FmD, filter paper with scent; FoD, filter paper without scent; Kk, cardboard box with lid removed; Kr, framework of the cardboard box (support for the ruby glass plate); Kst, box top (dark box); Rgp, ruby glass plate; YGr, Y-glass tube. b, Cross-section: Hp, fibreglass; Kk, cardboard box with lid; YGr, Y-glass tube; Kr, framework of the cardboard box; Kst, box top; Rgp, ruby glass plate

Fig. 2. Normal bee in the Y-tube (No. 157): without zig-zag movements the bee runs in a straight line towards the scented box. DK, scented box; DO, box without scent

Fig. 3. Run of bee No. 108. Right antenna amputated, left antenna fixed on the morphologically correct side of the body. Zig-zagging run as indicator of klinotactic orientation

Fig. 4. Alternative choice of differently handled bees when different quantities of scent are offered simultaneously from the left and from the right. a, Bees with one fixed antenna (left antenna cut off); b, normal bees; c, bees with one movable antenna (right antenna cut off); d, bees with both antennae fixed in normal position

(distance between the tips of the antennae, 7–8 mm), then still 83 per cent positive choices were recorded. The run itself is a straight line; once in a while a slight zig-zagging appears: time per run, 3.4 sec.

Bees which have one antenna fixed and the other cut off tend to show a bias toward the intact side. The results in finding the objective vary from one condition to another: if the scent is given on the antenna side, then 76.9 per cent of these bees run into the tube branch with the scent. On the contrary, if the scent is offered on the amputated side, only 39.9 per cent of these bees run into the scented branch. The run to the scent source is a distinct zig-zag run (Fig. 3). Furthermore, the runs are appreciably slower (4.6 sec running time). One can show that the side tendency, which is frequently explained as an osmotropotactic reaction, is superimposed by a klinotactic orientation component. There is, therefore, a tendency toward the intact side. If scent is offered simultaneously and at different concentrations in the left and right tube branches, then normal bees, bees with fixed antennae, and bees with one movable antenna all choose the higher concentration (Fig. 4). The different scent ratios,

Fig. 5. 'Absolute' value in orientation (absolute orientation performance coupled with the time necessary finding the goal). The 'absolute' value in orientation for normal bees set at 100 per cent. *a*, Normal bees; *b*, bees with one movable antenna (the second antenna is cut off); *c*, bees with both antennae fixed in normal position; *d*, bees with one fixed antenna (the second antenna is cut off). ●, Bees with one fixed antenna: scent is offered on the side without an antenna. ○, bees with one fixed antenna: scent offered on the antenna side

however, are analysed with varying success by the different bee groups (Fig. 4). Bees with one fixed antenna and the other antenna cut off compensate for the side tendency only, if the scent ratio is 1:4 and when the greater concentration is given on the side without antenna (Fig. 4, curve *a*).

This method allows one not only to separate the side tendency and its connected klinotactic orientation component from one another, it also gives the first hint of the integration process in the central nervous system. The scent gradient between the left and the right side must be 1:4, so that a difference in the information from two sides will be recorded in the central nervous system. This is effective for cases in which the klinotactic component is experimentally removed from the orientation act and only the tropotactic adjustment is allowed (experiments on bees with both antennae fixed in normal position). The same holds also for the information from one side when the tropotactic component is eliminated and only klinotactic adjustment is allowed (experiments on bees with one antenna free). By a combination of tropotactic and klinotactic adjustment the central nervous system can detect smaller concentration differences (experiments on normal bees being about a ratio of 1:2).

Olfactory perception of the attracting scent therefore consists of two components: perception of the concentration gradient simultaneously in space and successive perception in time. The simultaneous component demands paired, symmetrically arranged receptors—at least two; they do not need to be movable. The successive component requires movement of the sense organ (theoretically one receptor would be enough) or movement of the animal. Normal bees use both these components in coupled ways. Bees with one antenna can only use successive perception of the concentration for orientation. The net performance in scent orientation (calculated in percentages) is almost equal for normal bees (87.0 per cent), for bees with one movable antenna (78.8 per cent), and for bees with fixed antennae (83.8 per cent). However, the individual groups approach the goal with different velocity ($P < 0.0027$). The net performance in scent orientation coupled with this time factor gives the 'absolute' value of orientation (Fig. 5). It shows us quite clearly the true grade of performance in olfactory orientation.

(2) *Crossing the antennae.* The antennae of bees which were trained to odorants are crossed at the scapus and fixed into this position (Fig. 6). By this crossing, the

instinctive, natural side-correct evaluation of information is no longer given. Bees with crossed, fixed antennae turn spontaneously and without hesitation at the point of decision into the scentless tube branch. This 'changing of polarity' of the antennae causes the olfactory information in the central nervous system to be recorded as reversed. It also causes differences to be sent out side-reversed. This way brings about the 'spontaneous turning' into the tube branch without scent. Their behaviour shows that they perceive the scent gradient spatially simultaneously between the antennae.

If the tips of the symmetrically crossed antennae are placed closer together, step by step along the median line, then a change from osmotropotaxis to klinotaxis occurs when the distance between the tips of the antennae is 2.0 mm (Table 1). This reaction is quite definite. If the distance is smaller than 2.0 mm, then the bees turn into the tube branch with the scent and make a zig-zag run to the scented box. This means, therefore, that simultaneous-spatial distinctions are no longer made, and only temporal sequences can be evaluated. Quite astonishingly, in antenna positions I-V, almost the same number of 'side-reversed correct' choices are made (see Table 1). The change from one orientation type to the other does not happen gradually, but rather suddenly. With asymmetrical crossing of the antennae (Fig. 7) the 'effective' boundary distance totals 2.7 mm.

Fig. 6. Bee head with symmetrically crossed and fixed antennae. The sections I, II, III, IV, V and VI give the possible position of the antennae during the experimental series. If the antennae are in position VI, then the bees orient themselves klinotactically; in all the other positions, osmotropotactically

Fig. 7. Schematic representation of a bee head with asymmetrically crossed antennae. Both antennae are fixed on one morphological side of the body. *s*, 'Effective' distance between the antennae tips

Table 1. CHOICES FOR THE BRANCHES OF THE Y-TUBE FROM BEES THE ANTENNAE OF WHICH ARE GLUED AND SWITCHED TO THE OPPOSITE SIDE AT VARIOUS DIFFERENT ANGLES

Position of the crossed antennae	Scent from the right (0.002 ml. anise oil)					
	I	II	III	IV	V	VI
'Correct', side-reversed choices (%)	79.9	76.6	72.4	77.5	74.3	23.4
Total number of choices	194	205	181	111	202	124
Distance between the antenna tips in mm	9-7	7-5	5-4	4-3	3-2	2-0

Osmoklinotactic orientation behaviour appears also when one antenna is fixed and the second antenna is left free, provided that the 'median distance' of the fixed antenna (Fig. 8) is smaller than 2.5 mm. The movable antenna can compensate for the false report of the crossed, fixed antenna only so long as the 'median distance' of the second antenna does not exceed 2.5 mm (Fig. 9).

(3) *Quantitative effect of osmotropotaxis.* How great must the difference of concentration between the left and the right antenna be in order to be perceived osmotropotactically?

Fine glass capillaries of a certain weight and diameter are slipped over the antennae and are glued on the scapus (Fig. 10). (The bees are previously trained to the scent.)

Liquid paraffin with scent of different concentrations is placed in the capillaries to produce different scent

Fig. 8. Schematic representation of a bee head with one fixed and one movable antenna. Left antenna fixed on the right side of the head. Right antenna movable. *s*, Median distance (equals the projected, perpendicular distance in the horizontal plane between the stinocellus and the tip of the fixed antenna)

Fig. 9. Reaction curve of bees with one antenna fixed on the opposite side (with different-sized median distances) while the other antenna remains movable. Scent from one side (0.002 ml. oil of anise). Distance of the fixed antenna from the median line is given in mm. ●, Values for those which received the scent on the side without antenna; ○, values for those which received the scent on the antenna side

Fig. 10. Bee head with glass tubes slipped over the antennae. The scapus-head joint is blocked. *DPg*, Mixture of liquid paraffin with scent

Fig. 11. Experimental bee stuck on to the cork hemisphere. Only a part of the cork hemisphere, the 'running area', is illustrated. *DPg*, Mixture of liquid paraffin with scent; *Gk*, glass capillaries; *Kh*, cork half-sphere; *Kp*, pieces of cardboard; *Ks*, glue; *P*, pincers

recognition reactions by the two antennae. The insect in the experiment is placed on a movable cork hemisphere (diameter, 4 cm) and is held down by means of a small plate on its thorax (Fig. 11). Direction and strength of the reaction are read off by means of a pointer and a scale (Fig. 12). So long as a difference between scent concentrations in the right and the left capillaries can be perceived, a directed run towards the more strongly scented side occurs. That means that the hemisphere turns exactly opposite to the direction in which the animal would turn if it were not glued down. Therefore, if the higher concentration is found in the right capillary, then the animal tries to compensate for the difference of concentration by turning to the right; that results in the cork hemisphere being turned to the left.

The lower concentration, 'initial' concentration, is held constant in all experiments. The 'test' concentration is varied for each test (a turn of 90° is given the absolute value of 1).

With high initial concentrations (1/10,000) the osmotropotactic ability to discriminate different scent concentrations is of the ratio 1 : 10 (Fig. 13). The change to

osmoklinotaxis occurs gradually at this concentration level (Fig. 13, curve *a*). With low initial concentrations (1/100,000), the ability to analyse different scent concentrations is at a ratio of 1:2.5 (Fig. 14). Here the change to klinotactic orientation occurs suddenly (Fig. 13, curve *a*). Therefore the osmotropotactic threshold is not an absolute value, but rather it is a variable depending on the initial concentration. This is biologically significant for the evaluation of different scent zones through which a bee moves when it is approaching a scent source. It is especially shown in these experiments that the olfactory perception of scent differences can operate basically without anemotaxis. In Nature, of course, anemotaxis works along with osmotropotaxis.

Fig. 12. Representation of the experimental arrangement for determining the osmotropotactic threshold in the scent field. The cork hemisphere (3.1 g weight) can be turned almost without resistance. With the help of the attached pointer, the direction and the strength of the turning tendency per unit of time can be read off. A turn of 90° of the cork hemisphere—the direction does not matter—gives the relative value of 1

Fig. 13. The determination of the osmotropotactic threshold with high initial concentration (1/10,000). Scent oil: methylheptenone. The black columns give the concentration ratios in both capillaries: *a*, values from 0-3 min calculated from the beginning of the experiment; *b*, corresponding values in the 5-10 min period; *c*, Δ , values of 3-5 min. In the 3-5 min period the osmotropotactic reaction ends. The osmotropotactic threshold with high initial concentrations is at a concentration ratio of 1:10 between both antennae. *Dq*, Scent gradient quotient

Fig. 14. Determination of the osmotropotactic threshold with low initial concentration (1/100,000). Scent oil: methylheptenone. The osmotropotactic threshold with lower initial concentrations is at a concentration ratio of 1:2.5 between the antennae. The remaining explanation is the same as for Fig. 13

Noted also was that the determination of thresholds can be carried out very well on the basis of the osmotropotaxis (Table 2).

Table 2. DETERMINATION OF THE LEVEL OF METHYLHEPTENONE AND BROMSTYROL

For both substances the threshold is at a concentration of 1:200,000

Concentration	Methylheptenone		Bromstyrol	
	Scent choices (%)	0-5 min after releasing the scent (No.)	Scent choices (%)	0-5 min after releasing the scent (No.)
1:50,000	83.0	697	90.5	154
1:100,000	88.5	637	85.5	513
1:200,000	73.4	672	71.0	888
1:300,000	50.8	850	58.1	931

These experiments have demonstrated that osmotropotaxis together with osmoklinotaxis are of vital importance in the rich mosaic of orientation behaviour of bees.

LETTERS TO THE EDITOR

RADIO ASTRONOMY

Sky Brightness at 14.1 Mc/s

KNOWLEDGE of the intensity-frequency relation of extraterrestrial radio emission has been obtained from scaled aerial experiments at frequencies higher than 20 Mc/s (refs. 1 and 2) and from ground-based or satellite-borne radiometers operating below 10 Mc/s (refs. 3, 4 and 5). The low-frequency observations, whether ground-based or satellite-borne, are affected by the ionosphere. The consequence of these ionospheric effects has resulted in difficulties being experienced when reconciling the observations in frequency regions below 10 Mc/s with those above 20 Mc/s.

It has now been possible to extend the scaled aerial measurements of sky temperature down to a frequency of 14.1 Mc/s. The present sunspot minimum resulted in low values of the ionospheric critical frequencies, allowing unhampered night-time observations at this frequency. The frequency of the present observations is close to those used in satellite experiments of Hartz⁴ and Smith⁵, which provide good values of relative intensities below 10 Mc/s. No highly reliable absolute values of sky temperature were provided in these experiments. By joining the satellite results with our present 14 Mc/s results and our previous scaled aerial measurements, a curve of the sky brightness-frequency dependence is obtained for the frequency region 1–100 Mc/s.

The 14.1 Mc/s observations were made with a low-resolution aerial directed at the zenith ($\delta = -34^\circ$) which contains, at different times, the galactic centre, the disk and the south galactic pole. At 0800 and 1700 h R.A. 60 per cent of the radiation received originated from galactic latitudes $-20^\circ < b < 20^\circ$, while no radiation was received from this belt between 2130 and 0400 h R.A. The south galactic pole was in the centre of the beam at 0040 h R.A.

The aerial used was scaled from those previously used by us at frequencies 20, 30 and 85 Mc/s. An additional result was obtained at the frequency of 48.5 Mc/s.

The aerial consisted of a single half wave-length folded dipole suspended 0.25λ above a continuous mesh screen a wave-length square in area. The receiver was a switched radiometer using a B40B communications receiver preceded by a low-noise pre-amplifier of 75 Ω characteristic impedance. Calibration, which consisted of rematching the aerial and replacing it by a noise generator, was performed each hour. The noise generator used consisted of two CV2398 noise diodes in parallel, working into a 75 Ω load. The maximum temperature available from this generator was 80,000° K. This is well below the sky brightness temperature at 14.1 Mc/s. It was thus necessary either to amplify the noise signal or else attenuate the sky signal. Both methods were tried and found satisfactory. In practice, a 9 dB calibrated attenuator was inserted between the aerial and the receiver. The accuracy of the noise calibration was checked by comparing two different generators. The two systems reproduced calibrations to within 2 per cent.

Ionospheric effects are serious obstacles to reliable absolute measurements at this frequency. The two separate effects that need to be considered are absorption in the F layers and the 'iris' effect. All observations were carried out at night, thus avoiding D layer absorption. Absorption in the F layers has been theoretically investigated by Ellis⁶, using a model based on thermal loss by collision of electrons with ions and neutral atoms. The theoretical results obtained agreed with extinction curves

determined by Mitra and Shain⁷ and Steiger⁸ at 18 Mc/s. From our own results and ionospheric data from Camden, 15 km distant, it was possible to plot an extinction curve for each hour of R.A. At least five calibrated measurements were available for each hour spaced over 6 h local time. During the observing period, December 1964 to July 1965, the night-time values of f_oF_2 were almost always less than 4 Mc/s. This limited the extent of the extinction curves. For $f_oF_2 = 4$ Mc/s, absorption was observed to be less than 0.1 dB, agreeing with theory. The 'iris' effect produces total reflexion of galactic emission for zenith angles:

$$\chi \geq \cos^{-1} \frac{f_o F_2}{14.1 \text{ Mc/s}}$$

At such angles the Earth temperature of 300° K is reflected into the aerial beam. A calculation was made of the attenuation due to the iris effect and it was found to be negligible for f_oF_2 , less than 6 Mc/s.

In addition to correcting for the ionosphere an allowance was made for losses in the aerial system which amounted to 0.1 dB in the matching transformer and 0.1 dB in the balun. The mesh reflecting screen was assumed to be perfect.

Fig. 1 shows the observed sky temperatures as a function of right ascension for $\delta = -34^\circ$, after the foregoing corrections had been made. We note that the minimum occurs at 0400 with $T_B = 110,000^\circ$ K. At 0040 h R.A., when the south galactic pole is in the main beam, $T_B = 125,300^\circ$ K. Because of the low resolution of the aerial, temperatures observed when there is a sharp gradient of sky temperature in the main beam have little meaning and thus we have omitted results from 1600 h to 2000 h R.A. Overall accuracy is better than ± 7 per cent.

Fig. 2 shows the present flux measurement for the south polar region, together with other scaled aerial values and the two satellite observations. Absorption in ionized hydrogen regions is a minimum in the direction of the galactic poles, and thus Fig. 2 gives a good estimate of the synchrotron emission spectrum. We note that at 16 Mc/s the temperature spectral index β , ($T \propto \lambda^\beta$), has fallen from its high frequency value of 2.65 to 2.55 ± 0.15 .

Some caution needs to be observed when interpreting these results, since the observed sky temperatures include an isotropic extragalactic component superimposed on the galactic emission. The spectrum of this extragalactic component is thought to be steeper and thus would dominate at low frequencies. Using the scaled aerial results it should be possible to separate the galactic and extragalactic components if the two components

Fig. 1. Observed sky temperatures at 14.1 Mc/s, $\delta = -34^\circ$

Fig. 2. Brightness-frequency relation. Scaled aerial results above 10 Mc/s, satellite results below 10 Mc/s

have differing spectra. The separation will be discussed by us elsewhere.

We are now making a new series of observations with scaled aeriels of medium resolution.

ASTROPHYSICS

Pulsation Periods of General Relativistic Objects

THE pulsation period of the lowest radial mode for a spherical homogeneous object in Newtonian theory is¹ (if $\Gamma_1 = \text{const}$):

$$\tau = 2\pi[4\pi G\rho(\Gamma_1 - 4/3)]^{-1/2}$$

and if $\Gamma_1 - 4/3 > 0$, the period may vary over a wide range depending on the density.

However, a spherically symmetric homogeneous object in the post-Newtonian approximation has a period of²:

$$\tau = 2\pi c \left\{ 4\pi G\varepsilon(\Gamma_1 - 4/3) \left[1 - (GM/c^2 R) \left(\frac{10}{7} \Gamma_1 - 1 \right) \right] \right\}^{-1/2}$$

where ε is the total energy density. From this equation it is easily seen that there will be a minimum period even if $\Gamma_1 - 4/3$ is always positive and finite. Substituting:

$$\varepsilon = 3Mc^2/4\pi R^3$$

we obtain:

$$\tau = 2\pi \left\{ GMR^{-3}(3\Gamma_1 - 4) \left[1 - (GM/c^2 R) \left(\frac{10}{7} \Gamma_1 - 1 \right) \right] \right\}^{-1/2}$$

A very massive star (superstar) has a Γ_1 which is a function of mass and is approximately 4/3. The quantity $\Gamma_1 - 4/3 = \alpha(M/M_\odot)^{-1/2}$ (refs. 3 and 4). The minimum period will therefore occur at a radius of:

$$R = 76 \times GM/[63(\Gamma_1 - 4/3)c^2]$$

and:

$$\begin{aligned} \tau_{\min} &= (304 \times \pi GM/63c^3) (76/189)^{1/2} (\Gamma_1 - 4/3)^{-2} \\ &= 4.73 \times 10^{-5} \alpha^{-2} (M/M_\odot)^2 \text{ sec} \end{aligned}$$

or:

$$\tau_{\min} = 1.50 \times 10^{-12} \alpha^{-2} (M/M_\odot)^2 \text{ yr}$$

A superstar of $10^6 M_\odot$ would therefore have a period of (for $\alpha = 1.4$) 0.77 yr. If quasi-stellar sources are very large massive objects with fluctuations of the order of years, then one would not expect them to be much larger than $10^6 M_\odot$ because of the quadratic mass dependence of the periods. W. A. Fowler has recently pointed out that rotation may enable one to have smaller periods and therefore smaller radii.⁵

This general relativistic effect of a minimum period also manifests itself in neutron stars² and white dwarfs, although in these cases the models are not homogeneous and Γ_1 is not constant.

I thank A. D. Code for his advice.

Angular Momenta of Eclipsing Binaries and the Fission Theory of their Origin

IN a new development of the fission theory of the origin of close binary stars^{1,2} I showed that rotational instability would occur during the pre-main sequence contraction of rotating stars with no internal magnetic field. The theory predicted the observed mass range for contact binaries of W-Ursae Majoris type with satisfactory accuracy, and also gave the observed variation of angular momentum with mass for these systems. I now wish to show that the theory also predicts the observed relation between angular momentum and mass for all the close binary systems.

The rotational instability which gave rise to the formation of binary systems was due to the different behaviour of convective and radiative regions of stars. When the star is fully convective, as it is during early stages of contraction³, it rotates uniformly, and as the angular velocity increases the star spins off mass at the equator, and the effect of rotation is small over the bulk of the star. When the star begins to develop a radiative core, the rotation is no longer uniform as each element of the radiative core contracts, conserving its angular momentum. The parameter that measures the effect of rotation is:

$$\alpha = \frac{\Omega^2}{2\pi G \rho_c} \quad (1)$$

where Ω is the angular velocity and ρ_c the density at the centre of the star. When the star was fully convective, then with uniform rotation and centrifugal force balancing gravity at the surface, $\alpha = 0.04$ (ref. 4). With the development of the radiative core α varies like $\rho_c^{1/3}$ and so it will reach the critical value for instability, 0.187 (ref. 5), when ρ_c has increased by a factor 100.

The increase in ρ_c is due to two effects: the changing degree in central condensation due to the transition from convective energy transport, $\rho_c/\bar{\rho} = 6$, to radiative energy transport, $\rho_c/\bar{\rho} \approx 24$ for massive stars and 54 for small stars, and the increase in the mean density $\bar{\rho}$ due to the decrease in radius. As the readjustment in internal

structure takes place during a small change in radius, the central density will have increased to its critical value when the radius of the star has decreased by a factor of 2.3 for small stars and 3 for large stars.

The angular momentum of the star at the onset of rotational instability can be estimated. With centrifugal force balancing gravity, at the end of the fully convective stage the angular momentum is:

$$H_H = K G^{1/2} M^{3/2} R_H^{1/2} \quad (2)$$

where R_H is the radius of the star and $K^{1/2} R_H$ its radius of gyration. For a fully convective star $K \approx 0.13$ (ref. 4). During the fully convective phase it is known that the star has an approximately constant surface temperature $\approx 4,000^\circ \text{K}$. The radius R_H at which convection begins to die away can then be computed by equating the energy carried by radiation to the release of internal energy during the collapse of a fully convective star. This gives:

$$\lim_{r \rightarrow 0} \left[-\frac{4ac T^3}{3 \kappa \rho} \frac{dT}{dr} \right] = \frac{7 LP_c}{6 GM^2} R \quad (3)$$

where T is the temperature, κ the opacity, P_c the value of the pressure at the centre, a the radiation constant, c the velocity of light, L the luminosity $= \pi a c R^2 T_e^4$ (where $T_e \approx 4,000^\circ \text{K}$). With the opacity κ known as a function of pressure and density, and the temperature and pressure known in terms of the mass and radius for a fully convective star⁶ (a polytrope $n=1.5$) this is an equation to determine R_H , and hence from equation (2) H_H is known. Knowing the decrease in radius to the onset of instability we can get a lower bound on the angular momentum at the onset of instability, H_I , by neglecting the growing radiative core; an upper bound is obtained by assuming all the star is radiative. The actual value H_I must be somewhere between these limits, and we take the arithmetic mean^{1,2}. Since the decrease in radius to the onset of instability is at most by a factor of 3, and as the angular momentum varies like $R^{1/2}$ (equation 2) the lower bound on H_I is only less than H_H by at most 0.23 in the logarithm.

In Fig. 1 the predicted relation between angular momentum and mass of rotating stars at the onset of fissional instability is plotted, and also the observational values for all the close binary systems with spectroscopically determined mass ratios that are given in Kopal and Shapley's catalogue⁷, except for the few that are too massive to fit on our diagram. The agreement is very satisfactory.

The alternative theory of binary star formation, the capture theory, is unable to explain the observed correlation between mass and angular momentum, since the capture process is a chance phenomenon due to the close approach of two bodies in the presence of a third. There is no reason to suppose that this would give anything

other than a random distribution of masses and angular moments. The observed relation between mass and angular momentum lends support to the fission theory, and it is very satisfactory that the observations and predictions agree so well.

PHYSICS

Laser-induced Damage in Natural White Diamond

A PREVIOUS report¹ has described laser-induced damage in optically transparent materials such as glass, alkali halides, CaF_2 , MgO , sapphire and quartz; we wish to report the observation of this effect in natural white diamond. Intense, 0.3 joule, 10 MW pulses of 6943 Å radiation from a kryptocyanine Q-switched ruby were focused with a 5-cm focal-length lens on to the polished surfaces of the specimens. The dimensions of the specimens were very much smaller than the focal length of lens, thus ensuring that the power density of 10^9 W/cm^2 incident on the surface was constant throughout the specimen. The damage on the front surface was characterized by a seared mark apparently consisting of black carbon (Fig. 1), which indicated that a high surface temperature was attained. The rear surface damage was characterized by extensive fractures and cracking (Fig. 2). Because of the difficulty in sectioning diamond, it was not possible to determine the depth of the physical damage; however, as this was not observed on the front surface of the specimens it seems apparent that it is characteristic of the rear surface only. This is consistent with the observed damage in other optically transparent materials¹.

It has been proposed¹ that this damage is a result of acoustic phonons which travel in the forward direction through the material. These phonons are generated by stimulated Brillouin scattering of the laser light, and this process is similar to Raman laser action with the molecular vibration replaced by an acoustic wave. Other

Fig. 1. Angular momentum of close binaries

Fig. 1. Front surface ($\times 16$)

Fig. 2. Rear surface ($\times 16$)

damage mechanisms, such as direct heating from optical absorption and the interaction of light with material boundaries, were eliminated by detailed experiment. The acoustic phonon damage mechanism is supported by direct measurements of the frequency of the scattered radiation from the stimulated Raman process for quartz and sapphire².

The frequency of the acoustic phonon wave f is² $f = \frac{2f_1 v n}{c}$ where f_1 is the frequency of the incident light which is about 4×10^{14} c/s for ruby light, v is the velocity of sound in the material of refractive index n , and c is the velocity of light. For diamond, n is 2.4, and from measurements of the compressibility³ v is calculated as 1.8×10^6 cm/sec, whence f is about 120 Gc/s. This compares with 60 Gc/s for sapphire and 12 Gc/s for glass. The power in the acoustic wave is found from the ratio of the phonon to photon energies and is about 10^{-4} of the incident power or about 100 kW/cm² in these experiments.

These experiments were performed in an attempt to use a pulsed solid-state laser for the drilling of small holes in diamond. The results which we obtained show that the desired holes were not obtained because of the nature of damage mechanism.

Re-entrant Hysteresis Loop and Multistable Ferrites

It is well known that certain ferrites, especially CoFe ferrite¹, become magnetically anisotropic when heated in a magnetic field. This treatment results in an increased remanence ratio (I_{rem}/I_{sat}) and a square hysteresis loop. The explanation in terms of an ionic diffusion ordering process has been well developed². It is also well known³ that annealing in a unidirectional field results in a loop which appears displaced along the H -axis, but no adequate explanation has been given for the phenomenon in these materials. Glaister and Viney⁴ have reported re-entrant

hysteresis loops in these materials, and offered a tentative explanation for this phenomenon.

We have now prepared ferrite toroids with multistable remanent states in addition to re-entrant loops, and propose an explanation both for these effects and for the asymmetry resulting from a unidirectional field anneal. The material comprises $\text{Co}_{0.15}^{2+}\text{Fe}_{0.85}^{3+}\text{Fe}_2\text{O}_4$ and is sintered under conditions that result in slight oxidation of Fe^{2+} content; this deficiency yields cation vacancies and thus greatly increased mobility⁵ for the Co^{2+} ions responsible for anisotropy. On cooling, these ferrites show constricted or 'perminvar' loops. The samples are annealed in alternating fields of amplitude just sufficient to achieve technical saturation at 200° C and slowly cooled with the field applied. A very square re-entrant loop may then be observed (Fig. 1a) with a display system in which the magnetizing field is sensitive to the rate of change of flux⁴.

The flux reversal (switching) time of a square loop ferrite is equal to the quotient of the average distance traversed by the domain walls and the wall velocity. Thus the number of domain walls that participate in flux reversal is proportional to the reciprocal product of the domain wall velocity and the switching time (or wall mobility and switching constant). An estimate of this wall mobility using the treatment of Menyuk and Goodenough⁶ ($3,400 \text{ cm sec}^{-1} \text{ Oe}^{-1}$) and measurement of the switching constant ($500 \mu\text{s Oe}$) for a toroid with 4-mm wall section suggests that it is unlikely that more than one wall is involved in the flux reversal. Pulse measurements confirm that the rate of change of flux reversal is almost constant so that the comparison is valid.

Although samples with pronounced re-entrance are bistable and with slowly varying fields switch directly from one near-saturation state to the other, it is possible by applying single-shot pulses of about 2 μs duration to bring the domain wall to a central position giving zero net remanence. If the sample is then annealed in this state⁷ at 200° C a loop of the form shown in Fig. 2a is obtained; the zero-magnetization state has become stabilized and a field of 26 Oe in excess of the wall coercive field (20 Oe) is required to free the domain wall. Such cores have three stable states. Evidently the component of the field within the Bloch domain wall directed along the toroid axis has resulted in localized anisotropy with an easy axis perpendicular to the general circumferential direction.

Fig. 1. Cobalt-ferrous ferrite. (a) Annealed with alternating field giving re-entrant loop; (b) annealed with unidirectional field giving loop re-entrant in one sense only. Applied 50 c/s field 35 Oe pk

Fig. 2. Cobalt-ferrous ferrite. (a) Annealed in zero net remanence state giving tristable loop, and (b) annealed in intermediate remanence state. Applied 50 c/s field 17 Oe pk

By annealing a wall in an off-centre position, that is, with remanent magnetization between zero and full remanence, the relative position of the spikes on the two sides of the loop indicates whether the domain wall always moves in the same direction or oscillates to and fro. With the core geometry used (height greater than radial width) the spikes occur at the same flux-level (Fig. 2b) so that the wall evidently oscillates to and fro. Since cylindrical walls tend to move radially outwards, the field being strongest at the inner edge of the toroid, the movement is probably axial. Fig. 2b shows the loop resulting from the accidental annealing of two walls near one surface.

The same explanation holds for re-entrance; the wall is evidently not eliminated in the 'saturation' state and merely comes to rest near the sample surface. This is confirmed by the fact that excessive annealing fields which would tend to drive the wall out of the sample are found to reduce the re-entrance. The re-entrance of a partially annealed sample may be quite effectively increased by alternately switching from one remanent state to the other by the application of short pulses of alternate polarity (for example, 1-ms pulses with a pulse repetition frequency of 50 c/s). Thus annealing takes place substantially in the absence of an externally applied field. Further, when a unidirectional field is used for annealing, the loop is re-entrant on one side only (Fig. 1b). This would explain the asymmetry observed by previous workers using conventional display systems, for example, a ballistic galvanometer.

We thank G. W. Edwards for help with the experimental work and J. R. Halliwell for carrying out pulse measurements.

A Numerical Model of Random Packing of Spheres

A NUMERICAL approach using a digital computer has been used to construct a simple model of the unit cell in a randomly packed bed of identical hard spheres. The cell is built up by introducing spheres tangent to a central one at random positions around it. Each added sphere is accepted and its position recorded only if it does not overlap with any of the ones previously accepted. When there is no room for additional spheres, the cluster is complete and the volume of the unit cell is found. This unit is defined as the polyhedron formed by the perpendicular bisectors of the lines connecting the centre of the original sphere with its neighbours. There is some ambiguity in defining a unit cell in a random packing. The prescription used here has the justification that it is correct for the regular lattices with one sphere per unit cell such as the simple cubic, face centred cubic, and hexagonal close-packed arrangements.

Number of neighbours and cell volumes. An ensemble of about 3,000 of the clusters already described here was constructed.

Table 1. PACKING STATISTICS

<i>n</i>	Probability of <i>n</i> neighbours		Average cell volume for <i>n</i> nearest neighbours
	Touching	Within 1.35 diam.	
6	0.0054	0.0000	1.0349
7	0.0970	0.0026	0.9670
8	0.3878	0.1332	0.8924
9	0.3931	0.4316	0.8255
10	0.1137	0.3622	0.7688
11	0.0030	0.0638	0.7451
12	0.0000	0.0065	—
	$\bar{n} = 8.52$	9.37	$\bar{v} = 0.860$
	$\sqrt{\bar{n}^2 - \bar{n}^2}$	0.84	$\sqrt{\bar{v}^2 - \bar{v}^2}$

Table 1 gives the calculated frequency distributions of numbers of neighbours. In addition the average cell volume for each configuration is given, based on a unit ball diameter. Since just one ball is enclosed in the unit cell as defined here, the average solid fraction is given by:

$$f = (4/3)\pi(1/2)^3/0.860 = 0.609.$$

With the definition of the unit cell used here the proper solid fractions are obtained for the regular lattices as already mentioned.

Since packing densities between 0.61 and 0.64 have been found¹ depending on how well the bed of spheres has been shaken down, it appears that this model is describing a loose packing. This appears to be reasonable in view of the fact that no shaking down is allowed for in the process by which the ensemble of cells was constructed here.

In an experiment Bernal and Mason² found the mean number of contact points to be 8.5 counting only points in what they called total contact in a random close-packed assembly. Although this agrees superficially with the results obtained here, their distributions of numbers of contact points for both tight and loose packings were not the same as the present one. Fig. 1 shows the frequencies of various numbers of neighbours. Indeed, they observed cases with as few as four contact points. It is difficult to make a direct comparison with Bernal and Mason's results since their 'total contacts' include not only neighbours which touch the central ball but also neighbours somewhat farther out.

An attempt was made to include second neighbours in the cluster. This was done by filling in all the additional spheres that could rest without any overlapping on the stable positions determined by the nearest neighbours already found as described above. These positions were filled in random order.

Fig. 2 shows the density of ball centres as a function of distance from the centre of the cluster, both as found

here and as measured by Scott¹. The peak describing the first neighbours determined in the present calculation, which should actually be a delta function of area 8.52, is broadened in the plot to match the class width used by Scott in his measurement. It is clear from the plot that the second neighbours obtained by the process described here do not exhaust all the possibilities of nearby spheres.

Angular distribution. The angular distribution of neighbours around any given neighbour taken as a pole is shown in Fig. 3. Distributions are given for neighbours within 1.35 ball diameters as calculated here and as measured by Scott and Mader⁴. There is qualitative agreement between calculation and measurement, but the detailed shapes are not the same.

Method of calculation. The process of building up the cluster by introducing spheres at random positions around the central sphere becomes very inefficient when the cluster is nearly complete. This is because the remaining regions where neighbours can fit into the cluster become extremely narrow when the cluster is nearly complete. To speed up the calculation the actual computational scheme was modified as follows. After 250 possible neighbours were examined it was ascertained analytically whether and where there were gaps into which additional spheres could be fitted as neighbours. Each such gap was filled by inserting a ball at the centre of the gap. This introduced no discernible error since

Fig. 3. Angular distribution of neighbours

after 250 tries the latitude in placement of any additional sphere or spheres is extremely small.

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

METALLURGY

Slow-bend Testing of Hydrided Zirconium

THE embrittlement of zirconium by hydrogen is generally reflected by a decrease in the energy absorbed in fracture in an impact test, with a notched or unnotched specimen. Only in certain circumstances is a simultaneous reduction in ductility observed in a tensile test, and therefore the embrittlement has generally been considered attributable to high strain rates. However, some recent work we have carried out indicates that it is the actual mode of stressing—by bending—rather than the strain rate which promotes brittle fracture of hydrided zirconium in an impact test. Afterwards, slow-bend tests, both notched and unnotched, have proved useful in elucidating several of the factors which contribute to brittle fracture of zirconium. The relative unimportance of strain rate has been demonstrated by the occurrence of a brittle crack in a notched slow-bend test in which the bending to promote fracture took 48 h.

The slow-bend test also readily distinguishes between low-energy ductile failures and brittle cracks whereas the normal impact test does not. The three basic types of deformation curve obtained in slow-bend testing of hydrided zirconium are shown in Fig. 1, the deformation being taken simply as the movement of the straining head on the machine. The completely brittle specimen is typified by A which shows an elastic region I, and a plastic region II which varies slightly in extent. Once started, the crack is self-propagating, at a speed in the region of 25 m/sec, and needs no further deformation.

Fig. 1. Typical load-deformation curves for slow-bend tests on hydrided zirconium: A, Brittle fracture; B, low-energy ductile failure; C, high-energy ductile failure

On the other hand, a ductile specimen, as typified by C, requires continuous application of load throughout to promote propagation of a crack through the specimen, and therefore the rate of propagation is dependent on the rate of application of load. An additional region III in the curve represents the energy required for propagation.

Certain specimens give an intermediate type of curve, such as B, but the actual cracking is still ductile and requires a certain amount of further bending to cause propagation, but is preceded by a 'yield drop', during which 'ears' of plastic flow suddenly extend right across the sides of the specimen from the root of the notch, which has the effect of reducing the area of region III. Since the area under the deformation curve represents the energy required to fracture the specimen, as measured in a standard impact test, the usual impact test would not readily distinguish between a brittle specimen and a ductile one having a deformation curve of type B with an appreciable 'yield drop'.

It is interesting to note that the general shape of the load-deformation curves is similar to that of the load-time curves dynamically recorded by Fearnough and Hoy¹ during the Charpy impact testing of steels. Load-deformation curves for slow-bend tests are, however, much more readily obtained than load-time curves in a high-speed test.

Using a standard Hounsfield slow-bend specimen in the usual slow-bend jig, but attaching the latter to a hard beam testing machine, the effect of various variables on the hydrogen embrittlement of zirconium has been studied more effectively than could be accomplished by standard impact tests. The results indicate the importance of the 'yield drop' and its dependence on temperature, hydrogen content and inter-hydride spacing. The latter is a very important factor which may vary considerably with grain size and heat treatment even with a constant hydrogen content.

MINERALOGY

Structure of Interstratified (Mixed-layer) Minerals

MANY papers dealing with the structure of interstratified minerals such as illite-montmorillonite, chlorite-montmorillonite, chlorite-vermiculite, etc., have been published up to the present. In describing the structure of these minerals, the terms 'random' and 'regular' have been often used, but their definition is not very clear, since the term 'regular' has been applied mostly to '1:1 regular structure', whereas the term 'random' has been used for structures other than regular. It is necessary to investigate in detail the structure of interstratified minerals.

Suppose two kinds of layers, A and B, their number, N_A and N_B ($N_A + N_B = N$), and the potential energy between two layers, $-\varphi_{AA}$, $-\varphi_{AB}$, $-\varphi_{BA}$, $-\varphi_{BB}$, assuming the nearest-neighbour interactions, that are equivalent to Reichweite $g=1$. Then the total interaction energy (E) in a one-dimensional polar structure can be expressed by statistical mechanics as follows:

$$E = -\varphi_{AA}N_A - \varphi_{BB}N_B + \{\varphi_{AA} + \varphi_{BB} - (\varphi_{AB} + \varphi_{BA})\} \cdot N_{AB}$$

N_{AB} : the number of A-B pairs.

In the foregoing expression, $\varphi_{AA} + \varphi_{BB} < \varphi_{AB} + \varphi_{BA}$ is a condition necessary for the formation of the interstratified structure. For definite values of N_A and N_B , E is determined by the value of N_{AB} . This suggests that the stability of the structure increases energetically in proportion to the number of A-B pairs. We define here W_S as the probability of finding S layer at any position and P_{ST} as the probability of finding T layer succeeding S layer.

Then N_{AB} is shown as $N_{AB} = W_{AB} \cdot N = W_A \cdot P_{AB} \cdot N$, where W_{AB} is the probability of finding an A-B pair at any position.

Thus we can calculate the maximum value of W_{AB} for two cases, $g=0$ and $g=1$.

(a) For $g=0$ (random), which is a special case of $g=1$, the following relation holds: $P_{AB} = P_{BB} = W_B$, $P_{BA} = P_{AA} = W_A$.

In this case, W_{AB} equals $W_A \cdot W_B$, and this is the only one result given for $g=0$.

(b) For $g=1$, the maximum value of W_{AB} can be mathematically shown as follows:

$$(1) W_A = W_B \quad W_{AB} = 2 W_A \cdot W_B > W_A \cdot W_B \quad (g=0)$$

$$(2) W_A \neq W_B \quad (W_A > W_B) \quad W_{AB} = W_B > W_A \cdot W_B$$

In case (1), the relation of $P_{AA} = P_{BB} = 0$, $P_{BA} = P_{AB} = 1$ is held. This implies a 1:1 regular interstratified structure, ABABABAB. . . . In case (2), the relation

of $P_{BB}=0$, $P_{BA}=1$ is held. This implies a structure having no B - B pairs, being neither 'regular' nor 'random'. In this case two arrangements, $ABAAA$ and $ABAAABA$, are equivalent in the total interaction energy, having equal numbers of A - B pairs, so it is expected that all such possible arrangements would occur with equal probability for $g=1$.

Next we put $P_{AA}=\alpha$, $P_{AB}=1-\alpha$, $P_{BB}=\beta$, $P_{BA}=1-\beta$, then an equation $\beta=K\alpha+(1-K)$, where $K=W_A/W_B$, can be derived from the relation $\sum W_S P_{ST}=W_T$. Using this

equation all the interstratified structures consisting of two kinds of layers can be plotted on the graph shown in Fig. 1.

Fig. 1. The interstratified structure and some examples of illite-montmorillonite interstratified minerals examined

For example, the structure consisting of $W_A=0.6$, $W_B=0.4$, that is, $K=3/2$, is plotted on line (1), and $W_A=0.5$, $W_B=0.5$, on line (2). The random structures are on the diagonal dotted line (3). From the above view of interaction energy, it is expected that many interstratified minerals are distributed along or near the axes of co-ordinates.

In order to confirm this hypothesis, it is necessary to determine the values of W_A , W_B , α and β in a given specimen. Observed (00 ζ) reflexions of X-rays, where ζ is not an integer, were compared with mathematical intensity distribution due to one-dimensionally disordered structure. The equation used, which was presented by Kakinoki and Komura^{1,2}, is as follows:

$$I(\xi\eta\zeta) = N \bar{V}^2 + \sum_{m=1}^{N-1} (N-m) \text{Spur } \mathbf{V} \mathbf{F} \mathbf{Q}^m + \text{conj.}$$

\mathbf{V} is a matrix of layer-form factors V_S , \mathbf{F} is a matrix of W_S , \mathbf{Q} a matrix of P_{ST} multiplied by phase shift. N is the total number of layers. I programmed the equation for an electronic computer 'HIPAC 103', and the calculation for various combinations of W_A , W_B , α and β of illite-montmorillonite, chlorite-montmorillonite, etc., is now in progress. Results of some of the illite-montmorillonite interstratified minerals examined are plotted in Fig. 1.

(A) and (B) are from Kamisunagawa in Hokkaido³, (C) Honami mine in Nagano Pref.⁴, and (D) Kamikita mine in Aomori Pref.

(E), (F), (G) and (H) are the specimens investigated by MacEwan⁵ using the Fourier transform method. (I) is the 1:1 regular structures reported by other investigators^{4,6,7}. The result seems to support the foregoing view, and sug-

gests that it is necessary to treat the interstratified structures for $g \geq 1$, not $g=0$ (random).

CHEMISTRY

Resolution of the Optical Isomers of DL-Tryptophan, 5-Hydroxy-DL-tryptophan and 6-Hydroxy-DL-tryptophan by Paper and Thin-layer Chromatography

It is known that the optical isomers of many amino-acids can be metabolized by different pathways although it is often difficult to obtain suitable preparations for investigation. Several methods, both biological and chemical, are available for obtaining individual isomers in a pure state^{1,2}, but many of these tend to be practicable only if a large amount of the racemic form is available; yields obtained by classical chemical separation methods are low, while biological procedures usually lead to the destruction of one of the isomers. Separation has been achieved, however, by paper chromatography³⁻⁶. This approach seemed to be best suited to our requirement, the isolation of pure optical isomers of ¹⁴C-5-hydroxy-DL-tryptophan, a comparatively expensive compound. During our investigation, we noted that 5-hydroxy-DL-tryptophan (DL-5HTP), 6-hydroxy-DL-tryptophan (DL-6HTP) and DL-tryptophan (DL-TP) separated into two diffuse but distinct spots when chromatographed on Whatman No. 1 paper with butanol-pyridine-water (1:1:1, by vol.) as solvent system. The possibility of improving this separation by thin-layer chromatography was therefore explored.

Thin-layer plates (20 cm x 20 cm) were coated with a mixture obtained by homogenizing cellulose powder CC41 (Whatman, Ltd.) and water (1:2:3, w/v) for 30 sec at maximum speed in an M.S.E. blade homogenizer. A thin layer, 0.3 or 0.4 mm in thickness, was obtained by using a Camag applicator. Plates were air-dried overnight at room temperature, or oven-dried at 105° for 10 min. The compounds, dissolved in methanol or water, were applied to the thin layer and developed in the same solvent system as that used for paper chromatography. The solvent front was allowed to run for a distance of 10 cm which normally took about 1 h at room temperature. Plates were dried in a current of air at room temperature and sprayed with Ehrlich's reagent. The lowest concentration of DL-5HTP detected by this reagent was 0.05-0.1 µg. Table 1 shows the separation of isomers of the three amino-acids obtained by this technique.

It will be seen that the D-isomers of all three compounds have a greater R_F value than the corresponding L-isomers. D-5HTP used as a chromatographic marker was obtained by the action of L-amino-acid oxidase on DL-5HTP (ref. 7). L-5HTP was identified by incubation with guinea-pig kidney L-aromatic amino-acid decarboxylase⁸, followed by chromatography of the reaction products, which showed a disappearance of the L-5HTP and the

Table 1. R_F VALUES OF THE OPTICAL ISOMERS OF DL-TP, DL-5HTP, AND DL-6HTP CHROMATOGRAPHED ON CELLULOSE THIN LAYER IN BUTANOL-PYRIDINE-WATER (1:1:1) SOLVENT SYSTEM

	DL-TP	DL-5HTP	DL-6HTP
L-Isomer	0.52	0.47	0.36
D-Isomer	0.52	0.54	0.41

appearance of another spot, identified as 5-hydroxy-tryptamine. 6HTP was obtained presumably in the L-form from the hydroxylation of L-TP by *Chromobacterium violaceum*⁹.

To separate the isomers of DL-5HTP on a preparative scale, the compound was dissolved in methanol-0.1 N hydrochloric acid (5:1, by vol.) at a concentration of 25 mg/ml. and applied as a fine streak, 15 cm long, to a thin-layer plate. Using an applicator¹⁰, it is possible to apply several streaks on the same position after drying between each application. The application of two streaks was generally convenient, as this allowed the separation of about 1 mg of DL-5HTP. The chromatogram was developed in the solvent and, after drying, was sprayed with a 0.1 N solution of methanolic hydrochloric acid. The plate was viewed under ultra-violet light at 254 mμ (Camag 'Universal UV' lamp) and the outline of the two isomers delineated by their pink fluorescence. The CC41 powder corresponding to these areas was sucked into two tubes, each representing a different isomer. The powder was extracted with methanol and extracts were re-streaked and run on separate chromatograms. On viewing the two chromatograms under ultra-violet light, any contaminating isomer was seen to be well separated. Isomers were extracted with methanol as before and chromatographed, when each ran as a single spot.

When up to 1 mg of DL-5HTP is chromatographed, we have found that there is a certain amount of overlapping of the two isomers. By selecting the area of each isomer in such a way as to exclude this area of overlap, it is possible to obtain a fairly pure sample of each isomer in approximately 50 per cent yield. The area containing the mixed isomers could be kept separate and pooled with similar areas of other chromatograms. The pooled isomers could then be re-chromatographed to increase the overall recovery of the individual isomers.

Equilibration of the chromatogram for periods of up to one hour did not result in a better separation of the isomers; separation is, however, slightly improved if chromatography is carried out at 4°; this is presumably due to the increased developing time of the chromatogram.

We now hope to use this technique for separating the D- and L-isomers of ¹⁴C-5-hydroxy-DL-tryptophan for metabolic investigations.

We thank Dr. R. A. Ellis, of Sandoz, Ltd., for a gift of 6-hydroxy-DL-tryptophan.

This work was supported by grants from the Medical Research Council and the Peel Trust to each of us. We also thank Dr. M. Sandler for his advice.

Mechanism of Radical Decay in Irradiated Polyethylene

INVESTIGATIONS of the decay of free radicals in irradiated polyethylene demonstrate that the sec-alkyl radicals, formed with a *G*-value of about 3, decay at a significant rate at room temperature to leave a much smaller number

of allyl-type radicals that decay at a very much slower rate.

Although there is no direct proof that the cross-linking process involves combination of these free radicals, the correspondence in *G*-value between radical formation and cross-linking, and the fact that cross-linking results from ultra-violet irradiation in the presence of sensitizers¹, constitute strong evidence that cross-linking is a radical-combination process.

There has been much discussion in the literature as to whether the alkyl radicals decay by first-order or second-order kinetics. Lawton, Balwit and Powell² believed the decay to fit four first-order reactions with different decay constants. Cracco, Arvia and Dole³ fit their data with two first-order decay constants. Charlesby, Libby and Ormerod⁴, and Ormerod⁵, found their data to be consistent with a single decay constant of second order.

There is fairly general agreement that a very fast decay occurs in the initial stages, caused by a non-random distribution of radicals occasioned by their presence as near-neighbours. Since the initial deposition of energy in spurs would produce this distribution, it is not really necessary for this argument to postulate invariable production of radicals as near-neighbour pairs².

Since radical decay occurs even in the crystal⁷, where physical diffusion of the polymeric radicals and even significant segmental motion are prevented, it is necessary to postulate that either radicals are produced in very close proximity, or there is a chemical mode of radical migration. If the radicals are in groups in very close proximity, rate of decay should be first order, but there should be a continuous gradation of first-order rate constants, corresponding to near neighbours, more distant neighbours, and still more distant neighbour pairs reacting by limited segmental motion. If the radicals are not all in such close groups, a chemical mechanism for mobility must be present and the reaction will be second order after the initial combination of nearest neighbours.

Dole, Keeling and Rose⁸ first proposed that radical sites could migrate by what might be formulated as a succession of radical abstraction reactions:

in which the alkyl radicals are of the secondary type. Koritskii *et al.*⁹ supported this hypothesis. It is of interest to see whether known reaction rates for this reaction could provide a free radical diffusion constant that would give a second-order rate constant for radical decay that is of the right magnitude.

With each abstraction reaction the radical site moves an estimated 2.3 Å (average distance between hydrogens in the system). According to three-dimensional random walk theory, a radical which makes *n* jumps each of length *l* in random directions will travel a mean distance *r* from its starting point, given by:

$$r^2 = l^2 n$$

In particle theory the relationship of the diffusion constant to this mean square distance per unit time is given by:

$$D = \frac{1}{6} \frac{dr^2}{dt}$$

and we see no reason that this cannot be applied here as representing the constant for diffusion of the radical sites.

The relationship of a second-order rate constant to the diffusion constants of the reactants in a diffusion-controlled reaction is given by:

$$K = 4\pi r_0(D_1 + D_2)$$

where *r*₀ is the distance at which reaction will occur. In this instance, *K* is the diffusion-controlled rate constant for radical combination in this system.

From these expressions:

$$K = \frac{4\pi}{3} r_0 l^2 \frac{dn}{dt}$$

The reaction frequency, dn/dt , is the number of hydrogen abstractions per second undergone by each radical. This equals $K_a C_H$, where K_a is the rate constant for the abstraction reaction and C_H is the concentration of hydrogen atoms attached to secondary carbon atoms. The latter is equal to l^{-3} . We also assume r_0 is also approximately equal to l , the average distance between hydrogen atoms. From this:

$$K = \frac{4}{3} \pi K_a = 4.2 K_a$$

The diffusion-controlled rate constant for radical combination K can be calculated if we can determine the value of K_a . The rate constant K_a is not known for condensed phase and large molecules, and can only be estimated indirectly.

For gas phase, James and Steacie¹⁰ have determined the rate constant for abstractions of secondary hydrogens from *n*-heptane by ethyl radicals. If we consider the secondary hydrogens as one reactant, the rate constant at 25° is 120×10^{-23} c.c. molecule⁻¹ sec⁻¹.

No direct data are available on rate constants for such abstraction by secondary alkyl radicals. However, Kerr and Trotman-Dickenson¹¹ have tabulated such data for abstractions from aldehydes, and show that the rate constants for abstraction by isopropyl and *n*-propyl radicals are very nearly the same. Hoey and LeRoy¹² and Wijnen and Steacie¹³ provide data from which it can be concluded that the ratio of rate constants for the reactions $iPr \cdot + H_2 \rightarrow iPrH + H \cdot$ and $Et \cdot + H_2 \rightarrow EtH + H \cdot$ is about 0.2. On this basis we estimate the rate constant for abstraction of secondary hydrogens by secondary alkyl radicals to be roughly 40×10^{-23} c.c. molecule⁻¹ sec⁻¹.

If we can assume that this rate constant is applicable to segments of the polymer molecule in the amorphous phase above the glass transition temperature, we have as a diffusion-controlled rate constant for radical combination at 25°:

$$K = 4.2 K_a = 170 \times 10^{-23} \text{ c.c. radical}^{-1} \text{ sec}^{-1}$$

The second-order rate constants for free radical disappearance in irradiated polyethylene measured by Charlesby *et al.*⁵ have values ranging from 1×10^{-23} c.c. radical⁻¹ sec⁻¹ to 200×10^{-23} c.c. radical⁻¹ sec⁻¹. The higher value, obtained with high-pressure polyethylene, is in reasonable agreement with that calculated above. The low values were obtained with high-density, rather crystalline polyethylene. For these, the chains are held relatively immobile, and the gas-phase rate constant would be inapplicable on both steric and energetic grounds.

While the foregoing considerations seem of value for the bulk of the decay, the importance of the initial spur reaction must still be considered. The question involves the fraction of radicals that must react before the remainder can be assumed to have random distribution. Ohnishi's¹⁴ results have special significance here. He found that irradiation of linear polyethylene at -196° gave a steady-state radical concentration of 2.6×10^{-4} moles/g. At this concentration, the average separation of radicals is 18 Å, or, assuming grouping of four to a spur, the average separation of spurs is 30 Å. With this spacing, added ionization and excitation destroys as many radicals as it creates. Thus, at 50 Mrads, at which 90 per cent of the steady-state value is reached, spur overlap is already very serious, and the validity of any influence of non-random distribution is questionable at such high doses.

There has been much speculation about the role of hydrogen in enhancing mobility by the reactions:

Dole and Cracco¹⁵ demonstrated its occurrence at a rate paralleling the rate of decay of radicals; they found the exchange ceased when the alkyl radicals had disappeared. However, they calculated that an average of only one or two exchanges of this type occurred per alkyl radical. It

is of interest to calculate the rate expected from gas-phase rate constants.

Hoey and LeRoy¹² determined the activation energy for the reaction:

to be 12.5 kcal/mole. This is 1.2 kcal/mole larger than the similar quantity for the reaction of ethyl radical. Wijnen and Steacie¹³ determined the activation energy for ethyl + deuterium to be 13.3 kcal. If we, therefore, take 14.5 kcal/mole for the activation energy for the reaction:

and a steric factor of 10^{-3} , we obtain a rate constant at room temperature of about 1.3×10^{-23} c.c. molecule⁻¹ sec⁻¹. In the system of Dole and Cracco, assuming radicals in chain segments have a similar rate constant for reaction with D_2 and using their value for the concentration of deuterium in the solid, we calculate the frequency of reaction of a radical with D_2 should be:

$$\begin{aligned} 1.3(10^{-23})(C_{D_2}) &= 1.3(10^{-23})(1.2)(10^{-17}) = \\ &1.6 \times 10^{-6} \text{ reactions/sec} \end{aligned}$$

and a radical should react on the average once in 170 h. This is about a factor of ten longer than observed; but the agreement is reasonable for the approximations involved.

This reaction is about a million times slower than the abstraction from alkanes, which occurs about thirty times per second with each radical. Thus, it is difficult to understand how the presence of hydrogen enhances radical combination by a significant extent. Yet Smith and Jacobs⁴, Cracco, Arvia and Dole³, and especially Ormerod⁶, noted that presence of an atmosphere of hydrogen enhances the rate constant for radical combination by a factor of about ten. Thus, there is still no adequate explanation for this effect.

Irradiation Embrittlement of Low-boron Type 304 Stainless Steel

THERE is a growing amount of literature¹⁻⁷ that describes the magnitude and characteristics of the irradiation-induced embrittlement of alloys at high temperatures. These data appear to be consistent with the hypothesis that the grain boundary embrittlement is due to the helium generated by the $^{10}\text{B}(n, \alpha)$ (ref. 7) Li thermal neutron capture reaction^{1,8,9}.

This communication describes the effect of very small concentrations of boron on the irradiation embrittlement of 'type 304' stainless steel irradiated to a high exposure in a thermal neutron test reactor. These steels generally contain more than 1 p.p.m. B and it was necessary to electron-beam re-melt a commercial stainless steel to reduce the concentration of this element to very low values.

Five charges of approximately 650 g were prepared by cutting 1/4-in.-diameter rod into 2-in. lengths. The charges were melted using an 18-kW power-level and melting times of 4, 8, 12, 16 and 20 min. The resulting 'pancakes' were 4 in. in diameter and 7/16 in. thick. The chemistry of these pancakes is representative of the austenitic stainless steel class.

The boron concentration was determined using the spark source mass spectrograph of the Mattauch-Herzog geometry, which utilizes a radio frequency spark to produce ionization of the sample. The resulting ions are focused according to energy and direction and collected on an Ilford 'Q II' photographic plate. Elements are identified by position on the plate and concentrations are estimated from the density of the line as compared with an internal standard. In all samples of this series ^{53}Cr was used as an internal standard. Chromium-53 is a minor isotope and was free of any interference from other constituents of the sample. The samples were sparked so that a maximum exposure of 0.3 microcoulomb was obtained. For samples suspected, or known, to have high boron content, a 0.1-microcoulomb exposure was obtained. Detection limit varied from 5×10^{-9} to 8×10^{-8} atom fraction depending on exposure, plate and sample. In no case was the boron concentration lower than the detection limit for that sample. Results are summarized in Table 1. These data are believed to be accurate to within ± 50 per cent.

Table 1. BORON CONCENTRATION BY WEIGHT

After the various heats had been analysed, the electron-beam melted alloys and the commercial heat (in the as-received condition) were machined into subsize tensile specimens which were then irradiated in the core of the Oak Ridge Research Reactor at a temperature of 700° C. The samples were then removed from the reactor and tension-tested in a hot cell using an Instron machine. The post-irradiation ductilities, as given by the true uniform strain and total elongation, are listed in Table 2 for deformation at 704° and 842° C.

Table 2. EMBRITTLEMENT OF STAINLESS STEEL IRRADIATED AT 700° C

Tensile test temperature (° C)	Natural boron concentration (p p m.)	Ductility*			
		True uniform strain† Irradiated (%)	Unirradiated (%)	Total elongation Irradiated (%)	Unirradiated (%)

	0 130	3.3	18.2	6.1	57.2
	3.9	1.5	16.0	3.0	43.0

* Irradiated at B-8 position of the Oak Ridge Research Reactor to a neutron dose of 4.5×10^{20} neutrons/cm² (thermal) and 3.5×10^{20} neutrons/cm² ($E > 1$ MeV).

† Specimens strained at a rate of 0.2 per cent/min

Only small variations are found in the ductilities of all the electron-beam melted heats, although an order of magnitude exists between the concentrations of boron. The largest difference in ductility exists between the commercial alloy and the electron-beam re-melted alloys. The concentrations of helium were calculated for the ^{10}B reaction for each of the alloys and are given in Table 3. If one considers only the (n, α) reactions due to thermal neutrons, these data suggest that helium is not responsible for the embrittlement or that the embrittlement is quite independent of helium concentrations in the range of $0.13 - 1.1 \times 10^{-7}$ atom fraction. However, if one computes the concentration of helium due to fast neutron (n, α) reactions for all the elements present in stainless steel, then these data appear more compatible

Table 3. APPROXIMATE HELIUM CONCENTRATION FROM ALL (n, α) REACTION:

Alloy No.	Natural boron concentration (p p m.)	Helium concentration (atom fraction)		Total $\times 10^{-6}$
		Due to ^{10}B and thermal neutrons $\times 10^{-3}$	Due to fast neutron reactions $\times 10^{-4}$	
EBM707	0 015	0 013	0.3	0 313
EBM710	0 023	0 020	0.3	0 320
EBM709	0 107	0 091	0.3	0.391
EBM706	0 130	0 110	0.3	0 410
18141BC	3.9	3.3	0.3	3.6

with an irradiation embrittlement mechanism based on helium. The concentration of helium due to the (n, α) reactions with fast neutrons is also given in Table 3; these data were taken from the work of Bush, Motteff and Weir¹⁰. Considering the helium from all sources, the lack of variation in ductility of the electron-beam melted heats is more easily explained since the difference in total helium concentration is less than a factor of 2. This suggests that the irradiation of these electron-beam melted alloys in a more thermal neutron environment or to a lower fast neutron dose would result in a greater variation in the ductilities.

It is concluded that removing the ^{10}B from the alloy is not the ultimate solution for improving the ductility of irradiated alloys because, even in thermal neutron reactors, (n, α) reactions with fast neutrons are important, particularly for materials containing low boron.

We thank G. E. Angel for help in the preparation of the alloys, J. W. Woods for irradiation of the alloys, and K. W. Boling for the mechanical property tests. We also thank W. D. Harman and E. B. Griffen, of the Special Mass Spectrometry Laboratory, for their help. This work was supported by the U.S. Atomic Energy Commission under contract with Union Carbide Corporation.

Boron-Nitrogen Bond Strengths in Borazoles

THE bond order of boron-nitrogen compounds and the aromatic character of borazoles have been subjects of interest for many years (see, for example, ref. 1). It is shown here that bond energy terms and bond length measurements give apparently conflicting information about the relative strengths of some boron-nitrogen bonds.

The heats of hydrolysis in water at 25° C of *N*-trimethylborazole, borazole and *B*-trichloroborazole are -0.7 ± 0.1 , -19.7 ± 0.3 , and -113.6 ± 0.2 kcal/mole respectively. The value for *B*-trichloroborazole agrees with the previously reported² value of -113.8 ± 0.7 kcal/mole. The standard heats of formation of the compounds are -232.3 ± 0.1 , -204.9 ± 0.3 , and -256.1 ± 0.2 kcal/mole respectively. This value for borazole differs significantly from -131.1 ± 3.2 kcal/

Table 1 BORON-NITROGEN BONDS

Compound	<i>E</i> (kcal/mole)	<i>r</i> (Å)	Ref.

mole deduced from the heat of combustion³. The boron-nitrogen bond energy terms, calculated from the standard heats of formation, the heats of vaporization or sublimation⁴, the heats of atomization of the elements⁵, and bond energy terms characteristic of other bonds in the molecules⁵, decrease in the order:

Bond energy terms, *E*, and internuclear distances, *r*, of the boron-nitrogen bonds in the three compounds are compared in Table 1. The differences between the bond length measurements are small compared with the experimental errors, but both series of measurements indicate that the boron-nitrogen bond order is greater in *N*-trimethylborazole than in borazole. The thermochemical data suggest that the bond order is least in the case of *B*-trichloroborazole. This is in qualitative agreement with the original interpretation of the ultra-violet spectra¹¹ and with the relative values of the diamagnetic anisotropy of borazole and *B*-trichloroborazole¹².

Determination of p.p.m. Concentrations of Carbon Disulphide in Benzene by Electron Capture Gas Chromatography

THE highly specific response of the Lovelock electron capture detector toward certain functional groups has been exploited in various ways, notably in the detection of trace amounts of halogenated compounds¹.

In this laboratory the electron capture detector has been found to be extremely sensitive to carbon disulphide, and the presence of low concentrations of this compound is readily detected in hydrocarbon solvents. In the case of benzene, the S.T.P.T.C. standard colorimetric method² already exists, but the use of electron capture gas-liquid chromatography would appear to offer the advantages of increased analysis speed and improved accuracy.

A 10-ft. gas-liquid chromatography column is used to separate the CS₂ from other compounds. This is packed with 5 per cent w/w trixylenyl phosphate on 60/72 B.S.S. 'Celite' and operated at 70° C with nitrogen as carrier gas. The electron capture detector is of conventional construction with an internal volume of 1 ml. Tritium is used in the cell as a source of electrons and the cell is operated at a constant potential difference of 60 volts. A conven-

tional electrometer amplifier is connected to the detector and the output is measured on a 1-mV high-speed recorder after appropriate attenuation. A typical chromatogram of a 10-μl. sample of benzene containing 1.0 p.p.m. by weight sulphur as CS₂ is shown in Fig. 1.

Fig. 2 shows the relationship between CS₂ peak height and concentration. The graphs were obtained from standard solutions of CS₂ in benzene prepared by the S.T.P.T.C. procedure (ref. 2). A sample volume of 10 μl. was used for the range 0.1–1.0 p.p.m. and a volume of 1.0 μl. for the range 1.0–10.0 p.p.m., precision microsyringes being used in each case.

The results are linear over both ranges, although the lower concentration range shows a slight deviation from the origin. The lowest concentration of CS₂ used in the calibration, namely 0.1 p.p.m., corresponds to a peak height of 0.5 cm and this was clearly seen against the background noise. The minimum limit detectable would be about 0.05 p.p.m. which would correspond to a signal-to-noise ratio of 2:1.

Parallel calibrations were also made of the S.T.P.T.C. standard method. This involves measuring the optical

Fig. 1. Electron capture chromatogram of benzene containing 1.0 p.p.m. CS₂. a, Paraffins; b, CS₂; c, cyclohexane; d, benzene; e, toluene

Fig. 2. Relationship between CS₂ peak height and electron capture response

density of the colour formed, after the addition of copper acetate and diethylamine, by means of a photoelectric absorptiometer. The graphs showed considerable deviations from linearity outside the range 0.5–5.0 p.p.m. CS_2 .

Table 1 shows a comparison of the two methods when used for the analysis of three benzene samples.

Table 1. SULPHUR AS CARBON DISULPHIDE (P.P.M. BY WEIGHT)
S.T.P.T.C. standard method G.L.C. method

Sample 1	6.3	6.4
Sample 2	0.4	<0.1
Sample 3	0.3	<0.1

A good agreement is obtained in the case of sample 1 having a relatively high CS_2 content.

The gas-liquid chromatography (G.L.C.) method is probably more accurate than the S.T.P.T.C. method with samples 2 and 3, since these results were based on the absence of any CS_2 peak, in contrast with a calibration sample containing 0.1 p.p.m. of this compound.

Table 2

Injection number	1	2	3	4	5	6	7	8	9	10
Peak ht. (cm)	10.50	10.76	11.21	10.95	10.65	10.95	10.75	11.15	11.35	11.15
Mean peak height	= 10.94 cm									
Standard deviation	= 0.274 cm									
Per cent standard deviation	= 2.5									

Table 2 gives the results of ten repeat injections of a 10- μ l. sample of benzene containing 1.0 p.p.m. sulphur as CS_2 .

The results indicate a relatively high degree of repeatability for this type of analysis.

Separation of Coumarins

By sorption on ion exchange resins¹⁻³ it is possible to separate some coumarins in dilute solution. A column of the strongly basic anion exchange resin, 'Amberlite IRA-400' (-40, +60 mesh; Rohm and Haas Co.), in the chloride form (bed length, 50 cm; bed volume, 25.8 c.c.) has been used for this purpose.

The coumarins studied were of three groups. Group A includes coumarin (I), 3-Me(I), 7-Me(I), 3,4-di Me(I), 6,7-di MeO-4-Me(I) and 7,8-di MeO(I); group B includes 7-OH(I) and 8-OH(I); group C includes 6,7-di OH-4-Me(I) and 7,8-di OH-4-Me(I).

In a run, 50 ml. 5.636×10^{-4} M solution of one of the above coumarins in 10 per cent methanol (by volume) was passed through the column at 5 ml./min and the sorbed solute on the column was eluted. The effluent was collected in samples and estimated for the solute content by ultra-violet absorption⁴. Group A compounds were eluted by 10 per cent methanol. Group B compounds were not eluted by 10 per cent methanol, but were slowly eluted by N/10 HCl in 10 per cent methanol. Group C compounds were not eluted by 10 per cent methanol or by N/10 HCl in 10 per cent methanol, but were eluted by N/100 HCl in methanol. It is therefore possible to separate binary and ternary mixtures containing not more than one compound from each group.

BIOCHEMISTRY

Altered Electrophoretic Mobilities of some Erythrocytic Enzymes as a Function of their Age

A NUMBER of recent reports^{1,2} have indicated that the *in vitro* storage of human red blood cells leads to an increased electrophoretic mobility of some enzymes (for example, glucose-6-phosphate dehydrogenase, acid phosphatases) when compared with the mobility of the same enzyme obtained from fresh blood. This finding parallels that previously reported for haemoglobin derived from fresh or stored red cells³.

The availability of several methods for the separation of young and old red blood cells or of their lysates from a red blood cell population⁴⁻⁶ prompted us to investigate the electrophoretic behaviour of some enzymes derived from erythrocytes of different ages. This communication presents results of preliminary experiments indicating an altered electrophoretic mobility of some erythrocytic enzymes as a function of the age of the red cell from which they are derived.

It was also found that this altered electrophoretic behaviour is not shared by all erythrocytic enzymes, nor even necessarily by enzymes having the same substrate specificities but originating in different aged erythrocytes of other species. The implications of these experiments are briefly discussed.

100 ml. of human blood, collected in EDTA or acid-citrate-dextrose solutions, were washed six times with isotonic saline, great care being taken to remove the buffy white blood cell layer. The washed red cells were then subjected to the serial osmotic haemolysis procedure of Simon and Topper⁴ in which lysates from young and old erythrocytes are obtained separately. The smallest possible lysing volumes were used so as to have a high enzyme content per unit volume. Lysates were centrifuged at high speed (13,000g for 10 min) to remove the stroma. The haemolysates corresponding to the reticulocytes were not examined.

Control experiments on the behaviour of white blood cells in the serial osmotic haemolysis procedure indicated that the contribution of enzymes by residual, contaminating white blood cells in the red blood cells fractionated was small and most probably did not affect the results described here. Further experiments, however, using other separation procedures for young and old erythrocytes⁵ are in progress to confirm our results by another, independent method.

Glucose-6-phosphate dehydrogenase (G-6-PD) and glutamic-oxaloacetic transaminase (GOT) activities were assayed by standard spectrophotometric methods⁷⁻⁹ on the lysates of the youngest and older human erythrocytes. One unit of enzyme is defined as that amount required for a $\Delta O.D._{340} \text{ m}\mu$ of 0.001/min./ml. of lysate. For comparative purposes samples of blood were stored at 4°–5° C for up to four weeks. The latter samples were washed with saline after storage, lysed and enzyme activities determined as indicated above.

Starch-gel electrophoresis of G-6-PD was carried out according to the method of Fildes and Parr¹ except that, at these authors' suggestion, a 0.01 M phosphate buffer at pH 7.5 was substituted for the *tris* buffer described in their paper. GOT was electrophoresed following the method of Schwartz *et al.*¹⁰, but using a 0.01 M phosphate buffer at pH 7.3.

In all the electrophoretic runs the number of enzyme units of each lysate applied was identical to that of the fraction to which it was compared. About 10 units (as defined here) were applied for both G-6-PD and GOT.

Fildes and Parr¹ reported that G-6-PD has an increased electrophoretic mobility when the red blood cells from which it is derived have been stored. We have repeated these experiments and confirm their findings. The

difference in electrophoretic mobilities between fresh and stored G-6-PD is of the order of 10 per cent, although in some cases the difference has been appreciably greater. Our examination of GOT, obtained from fresh and stored red cells, revealed a smaller alteration in the electrophoretic mobility of this enzyme. These results, together with the described increase in electrophoretic mobilities of erythrocyte acid phosphatases², lead to the question of whether all erythrocytic enzymes manifest this behaviour. Examination of the electrophoretic behaviour of lactic acid dehydrogenase (LDH) isozymes¹¹ reveals that there is no alteration in the electrophoretic mobilities of these isozymes as a function of red blood cell storage *in vitro*. Thus, apparently, only certain enzymes display this behaviour.

Visualization after electrophoresis of G-6-PD and GOT derived from young or old erythrocytes reveals that the alteration in mobilities of these enzymes is not solely a function of their storage *in vitro*. These enzymes show a similar alteration in electrophoretic mobility on ageing *in vivo* (Figs. 1A and B). This may be analogous to results reported for haemoglobin in which haemoglobin A₂ (the old haemoglobin) displays an increased electrophoretic mobility¹² when compared with its younger counterpart (Hb A).

A number of suggestions have been made as to the possible cause of this increased mobility of haemoglobin on *in vivo* or *in vitro* ageing, one of which is that a mixed disulphide with glutathione is formed¹³ as a consequence of the diminished enzyme activities (for example, glutathione reductase) in older red cells. A number of other possibilities have also been discussed¹⁴ in view of the fact that a mixed disulphide formed between haemoglobin and glutathione *in vitro* has some properties that differ from those of Hb A₂ (ref. 3). In any event, whichever of the suggested reactions accounts for the alteration of the electrophoretic mobility of haemoglobin as a function of the age of the cell from which it is derived may well be similarly responsible for the altered mobilities of the G-6-PD and GOT, since all these proteins are contained in the same changing cellular environment.

That the reaction leading to the increased electrophoretic mobilities of erythrocytic enzymes is not one that occurs with all these enzymes is shown by the fact that LDH isozymes display neither a storage effect nor do they have altered mobilities as a function of the age of the red cell from which they are obtained¹¹.

Finally, investigation of the behaviour of G-6-PD from horse erythrocytes indicates that this enzyme (which in the horse consists of two isozymes) shows neither a storage effect nor an altered electrophoretic mobility as a

function of the age of the red blood cell from which it is derived.

It may well be that those enzymes which have certain reactive groups on their surface (for example, sulphhydryl) react with some reagent (for example, glutathione) as the cell ages and display the altered mobility observed on electrophoresis. Conversely, those enzymes not possessing such groups in readily accessible positions do not. If this is so, it might also serve as an indicator of this type of different molecular structure of some enzymes having similar substrate specificities but derived from different species (for example, G-6-PD from human and from horse). We are at present investigating some of these possibilities.

In conclusion: the examination of the electrophoretic mobilities of G-6-PD, GOT and LDH from young or old human erythrocytes reveals that G-6-PD and GOT derived from the older cells have increased electrophoretic mobilities while the LDH isozymes do not.

This work was supported in part by a grant (HE-08304) from the National Heart Institute, U.S. Public Health Service.

Note added in proof. Experiments conducted since this communication was submitted for publication in which human and horse haemolysates were reacted with oxidized glutathione and the resulting electrophoretic mobilities of the aforementioned enzymes compared to those from unreacted lysates indicate that human G-6-PD and GOT have increased electrophoretic mobilities after reacting with glutathione while human LDH and horse G-6-PD have not.

Deterioration of Stored Inulin Solutions

WHILE using a batch of inulin for determination of glomerular filtration rate in man, we found that some ampoules were giving much lower serum inulin-levels than were expected from the dose given. The inulin had been stored in the dark at 20°–25° C, in sealed ampoules, and from the batch number it was established that it had been manufactured thirteen years ago by Thomas Kerfoot and Co., Barnsley. We investigated the deterioration of inulin with time by determining the inulin content by the acid hydrolysis and resorcinol technique¹ in fifteen ampoules of the thirteen-year-old batch of inulin, in seven ampoules of inulin one-year old and in inulin recrystallized from the one-year-old batch, after washing with distilled water at 20° C. The ages of the inulin batches were kindly provided by the manufacturers.

Table 1 shows the results of total inulin content; taking recrystallized inulin as 100 per cent, the thirteen-year-old

INULIN ¹ CONTENT OF STORED INULIN AMPOULES

Table 2. AMOUNT OF REDUCING SUBSTANCES IN 10 PER CENT INULIN SOLUTIONS EXPRESSED AS FRUCTOSE (ref. 2)

Type of inulin	Fructose g/100 ml. in 10^{-4} per cent solution of inulin
(1) 13-year-old batch. First ampoule	5.05
(2) 13-year-old batch. Second ampoule	4.83
(3) 1-year-old batch. First ampoule	0.97
(4) 1-year-old batch. Second ampoule	1.42
(5) Recrystallized inulin	0.32

batch had a mean inulin content of 73.0 per cent *S.D.* 9.07, and the one-year-old batch had a mean inulin content of 88.9 per cent *S.D.* 2.36. Because the acid hydrolysis-resorcinol technique measures fructose and non-inulin fructose polymers, there must be considerable degradation of inulin to products other than fructose during prolonged storage. The true picture of how much inulin remains unaltered can be seen indirectly from Table 2, in which reducing substances were estimated by Benedict's quantitative method² in samples of thirteen-year-old inulin, one-year-old inulin and recrystallized inulin. It will be seen that about 5 g per cent of reducing substances (expressed as fructose) was present in 10 per cent inulin solutions thirteen years old, whereas 10 per cent inulin solutions one year old have between 1 and 1.5 g per cent reducing substances (as fructose) and 10 per cent solutions of recrystallized material contain 0.3 g per cent of reducing substances.

This work suggests that even one-year-old inulin contains appreciable amounts of non-inulin reducing substances, presumably fructose or fructose polymers; these may give falsely high values for plasma inulin re-absorption by the tubules³; a considerable error may be introduced into the measurement of glomerular filtration rate. It is concluded that for inulin-clearance measurements, solutions of inulin freshly prepared from recrystallized inulin should be used, and that inulin samples more than one year old should be discarded.

We thank Thomas Kerfoot and Co. for their help, and H. Varley for advice.

Interaction between Chlorophyll and Hydroquinone

CHLOROPHYLL has a unique characteristic in being photo-oxidized or photo-reduced by reactants which can serve as electron acceptors or donors to light-activated chlorophylls¹. The photo-reduction of chlorophyll occurs

when ascorbic acid is the reductant². Quinones act as electron acceptors for the photo-oxidation of chlorophyll³, but hydroquinones have not been shown to function as electron donors to the excited chlorophyll. It is known that hydroquinones are photo-oxidized by oxygen in chlorophyll *a* and *b* solutions⁴. The work recorded here consists of an experimental investigation of the direct interaction between excited chlorophyll and hydroquinone. The effect of oxygen on this system is also shown in this communication.

Chlorophyll *a* was prepared and purified by Zscheile's method⁵. Hydroquinone (Merck) was recrystallized four times from methanol solution. Photovoltaic changes of chlorophyll *a* with and without hydroquinone in methanol were measured by means of a Kintel digital voltmeter, model 456 B, with read-out, model 473 A. The photovoltaic cell consisted of a platinum electrode with a saturated calomel electrode as reference. The cell was irradiated through a collimating lens at a distance of 25 cm by a 1 kW-tungsten projection lamp. A Corning red filter OS-2-61 was used together with a 2 per cent copper sulphate solution. The solutions were flushed before and during measurements with nitrogen gas pre-treated with a chromous chloride solution. Electron spin resonance absorptions were determined by a Varian V-4502 equipped with 100-ke/s field modulation. The cavity of the EPR spectrometer was irradiated in the same way as in the measurement of photovoltaic changes. The solutions prior to irradiation were degassed on a vacuum line as described in the studies of the triplet state of chlorophyll⁶.

Fig. 1 shows the small photovoltaic change with chlorophyll *a* (7.4×10^{-4} M) in de-aerated methanol. Addition of hydroquinone to the same solution at a concentration of 10^{-4} M greatly enhances the photovoltaic change. The redox-potential of this system decreases in light and reverts to approximately the initial value when the light is turned off. This reversible change indicates an electron

Fig. 1. Photovoltaic change of chlorophyll *a* (a) and chlorophyll *a*-hydroquinone (b) in methanol: 7.4×10^{-4} M chlorophyll *a* and 10^{-4} M hydroquinone. Downward-pointing arrows show light on and upward-pointing arrows light off. Photovoltaic change is represented by $E_h - E_{cal}$, where E_h and E_{cal} are the redox-potential of the system and the electrode-potential of saturated calomel electrode, respectively

exchange between excited chlorophyll and hydroquinone. The negative change of the redox-potential on irradiation suggests that chlorophyll undergoes photo-reduction and its couple is responsible for the photovoltaic effect. The electron spin resonance measurements exhibited a greater rate of electron transfer than that found in the photovoltaic study. This difference is attributed to the slow electrochemical process at the electrode responding to the redox-reaction involving excited molecules in solution.

Electron spin resonance investigations showed that this photo-reversible change is due to one-electron transfer from hydroquinone to chlorophyll. Degassed solutions of chlorophyll *a* ($4.5\text{--}4.9 \times 10^{-4}$ M) with hydroquinone (10^{-2} M) in methanol exhibit two types of electron spin resonance signal when irradiated with red light as shown in Fig. 2*a*. One shows a hyperfine structure, which is characteristic of *p*-benzosemiquinone free radical, and the other is a broader signal probably from reduced chlorophyll. Fig. 3*a* illustrates a characteristic rapid rise and a quick decay of the signals.

In the presence of air, two similar types of signal were obtained and both were greatly enhanced (Fig. 2*b*). One, a single absorption, is a little broader than that in the air-free system. The other is the same as the afore-

mentioned signal having the hyperfine structure. The time to attain saturation of the signals was slower in the aerated solution than that found for the de-aerated solution as shown in Fig. 3*c*, especially the signal with the hyperfine structure which grew slowly during irradiation even after the broad signal had reached its saturation. The hyperfine signal decayed rapidly, while the decay of the broader signal was slower. With aerated chlorophyll *a*-methanol solution without hydroquinone, a smaller broad electron spin resonance signal is observed which is similar to the broad signal of the aerated chlorophyll *a*-hydroquinone solution. This indicates that these broad signals originate from an interaction between excited chlorophyll and oxygen. Chlorophyll *a* in methanol solution in air undergoes a permanent oxidation as evidenced by the decrease in electron spin resonance signal with continuous irradiation. The electron spin resonance decay of this solution was intermediate between that of chlorophyll *a* with hydroquinone and that with hydroquinone and oxygen (Fig. 3*b*). Calvin also showed this kind of electron spin resonance absorption in aerated methanol extract from *Chlorella*⁷.

Small photovoltaic changes obtained in anaerobic solutions of chlorophyll *a* in methanol are attributed to a reversible photo-bleaching of chlorophyll. This is consistent with a mechanism proposed by Livingston and Stockman⁸, where a very small amount of chlorophyll is reversibly photo-reduced by complexed methanol molecules.

The interaction between excited chlorophyll and hydroquinone shown in anaerobic solutions is significant for specific aspects of chlorophyll photochemistry. Very recently chlorophyll-photosensitized reduction of cytochrome *c* has been shown by chloroplasts or isolated chlorophyll *a* in the presence of hydroquinones. These reactions have been assumed to proceed via an initial photochemical reduction of quinone present as an impurity in hydroquinone⁹. Flash-illumination of chlorophyll solution containing reduced ubiquinone induced a rapid absorption change at 430 mμ, followed by a rapid decay which is slower than a decay of triplet state¹⁰. The work recorded here shows that the direct reaction of excited chlorophyll with hydroquinone is possible. Our investigation on the role of hydroquinone in the photo-reactions occurring in chloroplasts is now in progress.

The excited chlorophyll molecule undergoes reactions with oxygen to form an unstable, reactive complex^{11,12}. This occurs with the formation of free radicals and the subsequent permanent oxidation of chlorophyll¹³. In the presence of hydroquinone, the free radicals that are formed in the quick reaction of excited chlorophyll with oxygen probably undergo further reactions with hydroquinone to produce *p*-benzosemiquinone-free radicals in the oxidation of hydroquinone.

Biosynthesis of Triiodothyronine Sulphate by Beef Thyroid *in vitro*

It is well recognized that the thyroid gland contains the L-amino acids, triiodothyronine (T_3), thyroxine (T_4), monoiodotyrosine (MIT), diiodotyrosine (DIT) and iodinated thyronines which are free (unconjugated) but are bound to thyroglobulin. The release of these iodinated amino-acids occurs after digestion by protein-hydrolysing enzymes or chemicals, but the possibility of observing any T_3 and/or T_4 sulphate conjugates *per se* in thyroid tissues seems unlikely since hydrolytic procedures would have precluded their isolation.

The conversion of triiodothyronine (T_3) to triiodothyronine sulphate (T_3S) presumably occurs in the liver¹ since Roche, Michel, Closon, and Michel demonstrated the presence of T_3S in the bile and plasma of thyroidectomized rats. However, the well-established evidence for extra-hepatic mammalian steroid sulphokinase activity in endocrine glands such as adrenal^{2,3} and ovary⁴ stimulated an investigation of T_3 sulphokinase activity in mammalian thyroid tissues.

Fresh beef thyroid glands were homogenized at 4° C in 0.25 M sucrose, containing 0.05 M *tris* (tris hydroxymethyl aminomethane) and 0.002 M EDTA (ethylenediaminetetraacetate) at pH 7.5. The crude homogenate was filtered through cheese cloth and fractionated by ultracentrifugation according to the method of Fischer, Schultz and Oliner⁵. The fractions I-IV (see Table 1) were stored frozen until assayed.

The assay mixture included 100 μ mol imidazole HCl buffer, pH 7.0, 12.5 μ mol $MgCl_2$, 1.0 μ mol triiodothyronine (Sigma), 10 μ mol cysteine (neutralized), 10 μ mol K_4ATP , 10 μ mol K_2SO_4 , 0.2 ml. yeast sulphate-activating enzyme⁶ and 0.2 ml. thyroid sulphokinase fraction in a final volume of 1.0 ml. Incubation was carried out for 35 min in air at 37° C in the Dubnoff metabolic shaker.

Control flasks included zero time, and mixtures incubated without various components including enzymes. The T_3S was determined by the methylene blue method of Nose and Lipmann⁷. A standard curve was prepared by the use of the ammonium T_3S which was synthesized by the method of Fieser⁸. Protein was measured spectrophotometrically by the method of Gornall and colleagues⁹.

Table 1. T_3 SULPHOKINASE ACTIVITY OF BEEF THYROID
Fractional ultracentrifugation $m\mu$ mol T_3S formed per mg
of protein

Fraction I	Filtered crude homogenate	92
Fraction II	700g for 10 min supernatant	161
Fraction III	12,000g for 10 min supernatant	182
Fraction IV	105,000g for 60 min supernatant	216

The results of a typical incubation are listed in Table 1. The identification of ammonium T_3S sulphate in the incubation mixture followed the addition of concentrated ammonium hydroxide and extraction with *n*-butyl alcohol. Identical mobilities of the unknown and standard were observed after descending paper chromatography in the *n*-butyl alcohol, 2 N, NH_4OH system and paper electrophoresis in the $(NH_4)_2CO_3$, 0.05 M, pH 9 according to the methods of Roche *et al.*¹. The T_3S was located by positive ninhydrin stain and Schneider, Lewbart modification of the rhodizonic acid test for sulphate ions¹⁰.

The data indicate that T_3 sulphokinase activity is present in beef thyroid tissue and that the highest enzymatic activity is in the microsome-free supernatant. It is of interest that sulphokinase activity is also highest in the hepatic and adrenal microsome-free fraction, that is 105,000g supernatant. The thyroid T_3 sulphokinase activity remained constant for at least 3 months despite frequent freezing and thawing.

Preliminary studies suggest that beef thyroid microsome-free supernatant synthesizes T_4 sulphate (T_4S) in the same order of magnitude as T_3S (210 $m\mu$ mol per mg of protein per 35 min). Additional studies are in progress to purify T_3 and T_4 sulphokinase(s) and to study the enzyme kinetics involved.

I thank Drs. Arthur Schultz and Leo Oliner for supplying the initial frozen beef thyroid preparations. This work was supported by grant A-4783, National Institutes of Health, Division of Arthritis and Metabolism, Bethesda, Maryland.

PHYSIOLOGY

Effect of 'Furosemid' on Chloride and Water Excretion in Single Nephrons of the Kidney of the Rat

It has been shown by Muschaweck and Hajdú¹ that in the dog, at doses of 10 mg/kg body-wt. and more, 'Furosemid' (4-chloro-*N*-(2-furylmethyl)-5-sulphamoyl-anthranic acid) markedly increases the excretion of water, sodium and chloride. These authors also showed that the increase in chloride excretion was proportionally greater than that of sodium and water. On the other hand, Karger and Nagel² found a reduced permeability to anions, especially chloride, in the frog skin after addition of 'Furosemid' at concentrations of 25-500 mg/l. to the bathing solution, as evidenced by increased transmembrane potential differences without change in the short circuit current. Deetjen³ obtained proximal and distal tubular fluid samples in rats with an intravenous infusion of 2 mg/kg/min and observed significantly decreased proximal fluid/plasma (F/P) inulin ratios, as well as ratios below 2 in the distal tubule, concluding that 'Furosemid' depresses water and salt re-absorption in the proximal tubule and ascending limb of Henle's loop. Clearance studies by Suki, Rector and Seldin⁴ also indicated that 'Furosemid' might have an effect on the activity of the re-absorptive mechanisms of the proximal tubule and the ascending limb of Henle's loop.

Having this evidence in mind, we decided to investigate the fate of chloride along the nephron of the rat kidney, using micropuncture methods as described by Windhager and Giebisch⁵. Extreme care was taken in the collection of distal tubular samples, using rather long oil blocks (at least four times the tubular diameter), and checking the direction of flow by subsequent microdissection. Chloride and inulin were measured simultaneously, the first by the second coulometric method of Ramsay *et al.*⁶, the second by a modification of the microanthrone method of Hilger *et al.*⁷. 'Furosemid' was infused in saline (0.05 ml./min) at a rate of 0.8 to 1 mg/kg/min, sufficient to produce a marked diuresis. In parallel experiments the same measurements were done in control rats receiving saline infusion (0.05 ml./min) and in animals receiving a 4 per cent sodium chloride infusion at a rate of 0.1 ml./min.

Mean glomerular filtration rate (GFR) was 3.21 ml./kg/min in the 'Furosemid' group, 4.22 in the control group, and 5.77 in the 4 per cent sodium chloride group. Mean urinary pH was 6.32 (range 5.95-6.71) in the control group, 6.50 (5.99-6.83) in the 4 per cent sodium chloride infused, and 5.26 (4.76-5.82) in the 'Furosemid' group.

In Table 1a mean chloride F/P ratios in proximal and distal tubules, as well as chloride U/P ratios, are shown

Table 1

	(a) Chloride F/P ratios*						Urine		
	Proximal			Distal					
	Mean	Range	No.	Mean	Range	No.	Mean	Range	No.
Control	1.29	1.07-1.43	(12)	0.30	0.12-0.56	(15)	0.29	0.05-1.16	(11)
NaCl 4%	1.24	1.15-1.41	(8)	0.46	0.25-0.78	(10)	2.34	2.01-2.80	(7)

'Furosemid'	1.75	1.21-2.51	(7)	4.51	2.97-5.92	(9)	7.6	5.2-10.7	(15)

* Not corrected for an experimental ultrafiltrate/plasma ratio of 1.06.

n the 'Furosemid' and in the control groups. It can be seen that all three groups show similar proximal ratios, above unity. In the distal tubule, however, there is a marked difference between the control groups, having ratios significantly below unity, and the 'Furosemid' group, showing ratios consistently above one, similar to those observed in proximal tubules. There is a considerable rise in chloride ratios between distal tubules and collecting duct urine in the group receiving 4 per cent sodium chloride, but only very little further increase in the 'Furosemid' group. In Table 1b the corresponding inulin concentration ratios are seen. The proximal tubular inulin ratios are somewhat reduced, though not so much as those in the experiments of Deetjen³, probably due to our lower rate of infusion of 'Furosemid'. A larger reduction is observed in the early distal samples. On the other hand, it is noteworthy that there is little difference between the distal and urine inulin ratios in the 'Furosemid' group, as compared with the 4 per cent sodium chloride infused rats. The inulin ratios obtained in the latter group are similar to those obtained by Giebisch *et al.*⁸. Electrical potential difference measurements with glass microelectrodes in the 'Furosemid' infused rats showed proximal and distal transtubular potential differences within the range of controls (means -19.0 and -50.6 mV, respectively).

The results obtained in these experiments show that the mechanism of diuresis in rats undergoing 4 per cent sodium chloride infusion and during 'Furosemid' infusion is a quite different one, in spite of roughly similar overall chloride excretion rates (mean urinary Cl/inulin excretion rates of 0.13 in sodium chloride infused, and 0.19 in 'Furosemid' infused rats).

It appears that at our infusion rates of 'Furosemid' there is a relatively small inhibition of proximal and distal tubular fluid re-absorption. The major effect observed appears to be an impairment of the re-absorption of sodium chloride in excess of water in the ascending limb of Henle's loop, a process which constitutes the 'single effect' for the counter-current multiplier system of the renal medulla⁹. As shown by the high early distal chloride ratios in the 'Furosemid' group, the normally occurring hypotonicity of the tubular fluid at this site is absent, a further indication of impairment of the transport mechanisms in the ascending limb of Henle's loop. From our results, it appears that, due to inhibition of chloride and fluid re-absorption at this site, the build-up of a medullary salt concentration gradient might be impaired, as evidenced by the reduced further increase in the chloride and inulin F/P ratios between distal tubule and final urine. These experiments suggest, therefore, that 'Furosemid' in doses of 0.8-1 mg/kg body-wt./min acts preferentially on the sodium chloride transport system of the ascending limb of Henle's loop and the early distal convolution, preventing the establishment of a considerable concentration gradient for sodium chloride along these tubular segments.

Feeding and Reproduction of Rats fed Calcium Cyclamate

WITH the increased production and consumption of calcium cyclamate as a sweetening agent in foods for dietary uses, a series of feeding trials on rats was initiated at the request of, and under contract with, the Sugar Research Foundation, Inc.

Earlier work in this area was reported in 1951. Fitzhugh *et al.*¹ using rats as test subjects fed sodium cyclamate at levels up to 5 per cent in the diet for a two-year period. At levels below 1 per cent sodium cyclamate displayed little if any effect in the rat. At a level of 5 per cent in the diet, weight loss accompanied by moderate diarrhoea was reported. Histopathological examination of the animals was normal.

As this early work was performed with sodium cyclamate, and as the human consumption of calcium cyclamate has greatly increased during the intervening years, additional feeding trials appeared in order. The use of calcium cyclamate in human dietaries where reduced calorie intake is important led to the inclusion of feeding trials where calorie intake was restricted.

Weanling rats were placed on dietaries containing 5 and 10 per cent calcium cyclamate. Growth, food and water intake, and biochemical parameters were observed. After eight weeks on test, half the animals from each group were placed on restricted intake of food. These latter animals were limited to 60 per cent of the calorie intake of the animals receiving *ad lib.* feeding.

At eight weeks the females from each group were mated with males from their respective groups. Females were allowed to deliver their young and raise them to weanling stage (21 days). Following a rest period the females were mated a second time and allowed to raise their young to weanling age.

Haemoglobin and urine examinations were conducted at 6 and 8 months with selected animals. Selected

animals from the control group and the group receiving 10 per cent calcium cyclamate were killed at 6 months and examined histopathologically.

So far (9 months), body-weight and food consumption data have illustrated an effect of feeding calcium cyclamate in the diet, whether on full feed or on restricted feed intake. Animals receiving 10 per cent calcium cyclamate consumed approximately 10 per cent more diet than control animals. This increase in food intake compensated for the non-caloric cyclamate in the diet. Thus the 10 per cent calcium cyclamate rats' calorie intake was equal to the control animals. Despite equal calorie intake animals receiving calcium cyclamate at the 10 per cent level grew at a rate 20–30 per cent less than control animals. This growth depression results from the inclusion of the calcium cyclamate in the ration, but whether this is due to toxicity *per se* or an interference with nutrient absorption in the gastro-intestinal tract is being determined. Possible effect on metabolic rate is being examined. The same growth depression was noted to a lesser degree in animals receiving 5 per cent calcium cyclamate in their diet.

Animals in all groups were in good health. The faeces of animals receiving calcium cyclamate in the diet were soft and moist. Initial diarrhoea during the early weeks of the experiment disappeared after 8 weeks on test. No remarkable variation was noted among the rats during haematological or urine examination. Animals receiving calcium cyclamate consumed 25–40 per cent more water daily.

Animals receiving *ad lib.* feed conceived and were able to raise their young to weaning (21 days) during both breeding trials. In the first litters the control young averaged 50 g in weight at 21 days of age, the 5 per cent calcium cyclamate young averaged 42 g, and the 10 per cent calcium cyclamate young averaged 32 g.

In the second litter, control young averaged 52 g, 5 per cent calcium cyclamate young 45 g, and 10 per cent calcium cyclamate young 32 g.

Reproduction investigations using animals receiving restricted or limited food intake were carried out. These animals conceived, bore their young, but were unable to maintain them beyond 5 days of age.

In an effort to understand the reduced growth rates in animals receiving calcium cyclamate in the diet despite equal calorie intake a balance study was set up. This investigation indicated complete utilization of the ration based on nitrogen retention and faecal and urinary nutrient excretion.

Other parameters to understand these effects, including possible increased metabolic rates and ultimate fate of cyclamate, are being investigated.

Carbon Dioxide Production of Whole Blood *in vitro*

A RECENT publication¹ has shown the mean oxygen consumption of whole blood *in vitro* at 37° C to be 8.5×10^{-5} ml./ml./min, and the mean rate of increase of P_{CO_2} to be 0.11 mm mercury/min. The addition of sodium fluoride was found to reduce the oxygen consumption by 26 per cent and to prevent completely the rise of P_{CO_2} . The authors commented that their findings were paradoxical "because oxygen could not be consumed without production of carbon dioxide".

We believe this statement to be incorrect. Working in separate centres, we have reached the conclusion that carbon dioxide production of whole blood *in vitro* at normal P_{O_2} is negligible compared with its oxygen con-

Table 1

	Temp. (° C)	Method	Rate of fall of O_2 content ml./ml./min	Temp. (° C)	Method	Rate of fall of CO_2 con- tent ml./min
Capel and Fletcher	37	Modified Haldane	10.4×10^{-5}	30	Modified Haldane	2.1×10^{-5}
Nunn	38	Polarography at 100% saturation of haemoglobin	10.5×10^{-5}	38	Van Slyke	5.6×10^{-5}

sumption. We have, in fact, found the carbon dioxide content of blood to fall during storage, although our values for oxygen consumption are of the same order as those of Lenfant and Aucutt¹.

Our results suggest a negative respiratory quotient for whole blood at normal P_{O_2} although we agree closely with the rate of rise of P_{CO_2} reported by Lenfant and Aucutt¹. We believe that this rise cannot be due to carbon dioxide production and suggest that it is due to the production of non-gaseous acids. We have found that blood stored at 37° C develops a metabolic acidosis of the order of 0.03 m.equiv./l./min, a figure which is in close agreement with the rate of increase of lactic acid². It can easily be shown by the addition of lactic acid to blood (*in vitro*) that the production of lactic acid is sufficient to account for the rise in P_{CO_2} without invoking the production of carbon dioxide.

Transplantation Experiments on Placental Ageing

KROHN¹ has recently re-emphasized the role that transplantation studies can play in the elucidation of the process of ageing in organs and tissues. He has shown that skin and ovary have intrinsic life cycles, to a large extent independent of central mechanisms. These techniques have not been successfully used in the study of rapidly ageing transient tissues like the placenta. Earlier transplantation studies of placenta have always used allogeneic tissues, since the importance of genetic differences in such experiments was not appreciated². The present experiments, to be described in detail elsewhere, were designed to demonstrate the evolution of syngeneic transplants of mouse trophoblast with age.

Adult mice of the highly inbred strains C3H and C57 were mated (C3H female \times C3H male, C3H female \times C57 male, C57 female \times C3H male). The gestational age of each pregnancy was calculated from the day of the appearance of a copulation plug. The pregnancies were interrupted on gestational days 2, 7, 10, 15, 18 and 20. Recipient animals were adult male mice syngeneic to the donor tissue in all cases. At two and seven days, the fertilized ova and the ectoplacental cone were transplanted into the spleen or under the kidney capsule as previously described³. The placental rims of the older pregnancies were divided into 1-mm fragments and implanted into the spleen and under the kidney capsule. The recipients were killed 5, 10, 15 and 20 days after transplantation, and the tissue fixed in formalin. Haematoxylin and eosin staining was routinely carried out.

Trophoblast underwent active proliferation from the implanted ova and ectoplacental cones of the 2- and 7-day-old pregnancies and it was actively invasive of host tissue. A large amount of haemorrhage was present from eroded host vessels by five days after transplantation. Such transplanted trophoblast cells were of large size with long cytoplasmic processes, giant nuclei and prominent nucleoli. Living cells from such transplants could occasionally be found as long as 25 days after transplanta-

ion, but most frequently cells survived for only 15–20 days. Host cellular reaction was minimal. No definite cytolysis or phagocytosis of host tissue as reported by Kirby⁴ was seen nor was there any ingrowth of host capillaries into the graft. Trophoblast-free haemorrhagic cysts interspersed with shreds of eosinophilic hyaline material remained after cell death.

In contrast, no proliferation or invasion of host tissue was present in any of the transplants performed after 10 days gestation. Haemorrhage was elicited by the 10-day gestational placental transplant, but its appearance was delayed until 10 days after transplantation. No haemorrhage was present in any transplant older than 15 days gestation. Vascularization of the transplant did not take place.

A cell pattern similar to that of the original transplanted placental fragments could be seen in the older implants removed 5 days after transplantation. Such patterns disappeared from specimens taken 10 days after implantation. Generally the smaller trophoblastic cells peculiar to the labyrinth of the placenta disappeared with time and the proportion of giant cells increased. In the specimens taken 10–15 days after transplantation, the vacuolized eosinophilic cytoplasm of the remaining cells tended to coalesce with the loss of cell boundaries. Soon afterwards, the giant cells became swollen or disintegrated. The cytoplasm then lost its vacuoles and became hyalinized. In the 15–20 day specimens, viable cells were rare or absent and eosinophilic hyaline bands frequently occupied the entire implant. Extensive hyalinization was present as early as 5 and 10 days after transplantation in the 18-day and 20-day gestational transplants.

In conclusion, it would appear that the transplanted mouse trophoblast has an intrinsic life cycle which extends about 25–30 days after conception. Its ability to proliferate and actively invade tissue is lost by mid-gestation and its ability to elicit haemorrhage by eroding host blood vessels is lost soon thereafter. There is a suggestion that the trophoblast nuclei may increase in size with age and that cellular degeneration may be accompanied by formation of a symplasma, which is not normally found in the rodent placenta⁵. These results are consistent with the early cessation of trophoblastic invasion and its pattern of ageing and hyalinization *in utero*⁶. Since proliferation and invasion are such prominent features of young transplants into the adult male, it is unlikely that the loss of trophoblastic vigour, and death, are due primarily to a changing or unfavourable endocrine environment.

PHARMACOLOGY

Serotonin Depletion by Dietary Leucine

MAPLE syrup disease (branched-chain ketonuria) is an apparently familial disease associated with mental retardation and biochemically characterized by enhanced urinary excretion of branched-chain amino-acids and their products.

Few cases of this disease have been reported^{1–4} since its characterization by Menkes, Hurst and Craig in 1954 (ref. 5), and little is known about its biochemical basis beyond suggestive evidence implicating impaired oxidative decarboxylation of branch chain α -keto-acids⁶. Still less is known about the relationship between biochemical features of the disease and the attendant mental retardation.

Mental retardation is a prominent clinical feature both of maple syrup disease and the more familiar phenylketonuria, and attempts have been made, with some success, to establish corresponding biochemical similarities between these diseases. Thus, branched-chain and aromatic amino-acids, and/or their metabolites, inhibit rat brain decarboxylase⁷, serotonin and 5-hydroxytryptophan uptake by rat brain slices⁸, and, when added as a dietary supplement, reduce liver tryptophan hydroxylase activity⁹.

These similarities prompted us to determine whether the brain serotonin-level would be diminished by dietary leucine as it is by dietary phenylalanine¹⁰.

At 17 days of age litter-mate pairs of Sprague-Dawley rats¹¹, matched for age, weight and sex, were divided into control and experimental groups, housed in individual cages and fed *ad lib.* either a control diet¹¹ or the control diet supplemented with 5 or 8 per cent by weight of L-leucine¹². After 30–40 days on the diet, animals were killed by decapitation, the brain removed immediately, sectioned between medulla and spinal cord, rinsed in saline, blotted dry, and analysed for serotonin¹³. Statistical significance was determined using a *t* test for paired differences.

Brain serotonin-levels were diminished by dietary leucine in a manner analogous to that observed using dietary phenylalanine (Table 1). Experimental animals significantly differed from controls in both instances ($P < 0.05$).

Table 1. DEPLETION OF BRAIN SEROTONIN BY DIETARY LEUCINE

	Body-wt. (g) Mean \pm S.D.	Brain-wt. (g) Mean \pm S.D.	Serotonin (μ g/g brain) Mean \pm S.D.
Controls	187 \pm 8	1.726 \pm 0.048	0.609 \pm 0.033
5 per cent leucine	190 \pm 13	1.741 \pm 0.054	0.518 \pm 0.036
8 per cent leucine	170 \pm 8	1.626 \pm 0.024	0.473 \pm 0.010

Growth was impaired somewhat by 8 per cent but not 5 per cent leucine supplementation, although control animals did not significantly differ from those fed the 5 or 8 per cent diets because of the large variance in body-weights. Brain-weights reflected these differences in body-weight—animals on the 5 per cent diet having brains not significantly heavier than controls and animals on the 8 per cent diet having ones significantly lighter. The ratio of brain- to body-weight was essentially the same for all three groups.

Total brain serotonin was 1.084 μ g for controls, 0.969 μ g for the 5 per cent group and 0.863 μ g for the 8 per cent group, again indicating diminished serotonin with increased dietary leucine. Because of the differences in brain weight, however, the controls differed significantly only from the 8 per cent group ($P < 0.001$); the difference from the 5 per cent group reached the 0.1 level of statistical significance. Correcting for body-weight differences by calculating μ g serotonin/g brain/kg body-weight, the control value of 3.21 was significantly greater than 2.69 for the 5 per cent group ($P < 0.05$) but not significantly greater than the 2.78 for the 8 per cent group.

Despite these complications resulting from altered growth rates, it seems clear that dietary leucine supplementation lowers brain serotonin. It has been suggested¹⁴ that the decreased brain serotonin in the phenylalanine-fed animals is related to impairment in problem solving ability. The present finding suggests a possible common basis for the mental deficiency accompanying phenylketonuria and maple syrup disease.

IMMUNOLOGY

Mathematical Model for the Process of Aggregation in Immune Agglutination

IMMUNE haemagglutination is the combination of bivalent antibody molecules with specific antigenic determinants on the surface of red cells and the coincident collision of red cells resulting in the formation of antibody cross-linkages between cells and visible aggregation^{1,2}. As a means of characterizing immune haemagglutination, rates of red cell aggregation were examined with the aid of a Coulter electronic cell counter³. In the course of this examination it was empirically found that the initial decrease in free cell concentration followed an exponential decay curve. There was no basis, however, for considering aggregation to be a first-order reaction. Subsequent consideration suggested that aggregation involved an orderly sequence which might be expressed mathematically.

The mathematical representation of the rate of red cell aggregation presented in this report was arrived at through several series of experiments in which theoretical and experimental curves were compared. The eventual close approximation achieved between these curves tends to substantiate the validity of the equations from which the theoretical rate curves were derived.

The experimental curves were obtained by a procedure previously described in detail³. The rate of reduction in free cell concentration and total number of particles (total of free cells plus aggregates) was followed by means of the 'Model B' Coulter electronic cell counter (Coulter Electronics, Hialeah, Florida). Rates were determined under controlled conditions of antiserum concentration, cell concentration, temperature and speed of mechanical mixing. The reaction vessel of 150 ml. capacity was secured in a temperature control jacket, which fits on the stand of the Coulter counter. Agitation was accomplished with a spiral stirrer attached to a constant speed motor, 300 r.p.m. The 100- μ aperture tube had a sampling time of 15 sec. The temperature was maintained at 25° C.

With the double thresholds arrangement of the Coulter counter it was possible to follow experimentally the concentration of several different size aggregates, but because of practical limitations concerned with inhomogeneity in the size of red cells, and complications concerned with coincidence, only the total particle count was followed.

An initial lag period in the rate curve, due to the time required for the primary union of antibody and cells, was eliminated by incubating antiserum and cells without mechanical mixing³. At the antiserum and cell concentra-

tions employed in these experiments, a sensitization period between 30 and 80 min was sufficient to eliminate the lag period.

Several immune systems of different specificity were examined in these studies. Human A and B isoantibodies and human red cells of appropriate blood group were used in early experiments. Variation in the degree of fit between theoretical and experimental rate curves obtained with different cell populations suggested a heterogeneity of the red cell population with respect to their agglutinability⁴. It was found that this heterogeneity could be minimized with any of several antigens coupled to tanned red cells⁵. The agglutination obtained with human anti-A sera and purified hog A substance coupled to tanned group C human red cells was most intensively examined.

Immune aggregation can be defined as the change in state from free cells to aggregates due to the random collision of partially antibody-coated (sensitized) red cells. The random collision of sensitized cells leads to a progressive decrease in the number of free cells with a concomitant increase in the number of aggregates of larger size with time. Although the concentration of free cells would decrease throughout the process of aggregation, the concentration of progressively larger size aggregates would consecutively increase and then decrease as aggregation proceeds. The combinations which lead to the formation and subsequent decrease of different size aggregates are shown in Table 1. Based on these considerations a mathematical model for red cell aggregation was progressively developed. The present form of the model will be explained.

Table 1. COMBINATIONS WHICH INCREASE AND DECREASE THE CONCENTRATION OF DIFFERENT SIZE AGGREGATES

Aggregate size	Combinations which:	
	increase number of aggregates	decrease number of aggregates
1	0	(1,1) (1,2) ... (1,N)
2	(1,1)	(2,1) (2,2) ... (2,N)
3	(1,2)	(3,1) (3,2) ... (3,N)
4	(1,3) (2,2)	(4,1) (4,2) ... (4,N)
5	(1,4) (2,3)	(5,1) (5,2) ... (5,N)
6	(1,5) (2,4) (3,3)	(6,1) (6,2) ... (6,N)
7	(1,6) (2,5) (3,4)	(7,1) (7,2) ... (7,N)
8	(1,7) (2,6) (3,5) (4,4)	(8,1) (8,2) ... (8,N)
9	(1,8) (2,7) (3,6) (4,5)	(9,1) (9,2) ... (9,N)
10	(1,9) (2,8) (3,7) (4,6) (5,5)	(10,1) ... (10,N)
...		
N	(1,N-1).....	(N,1).....

It is assumed that there may be aggregates of 1, 2, 3 . . . N cells. The number of aggregates consisting of i cells at time t can be denoted by $X_i(t)$.

To analyse the change in $X_i(t)$ with time, let $A_{ij}(t)$ be the rate at which the number of aggregates of size i combine with aggregates of size j at time t . Notice that if $i=j$, then only $A_{ii}(t)/2$ aggregates of size $2i$ are produced. To make this clear, consider the following two examples. If 5 aggregates of size 3 combine with 5 of size 4, then $A_{34}(t)=5$ and 5 aggregates of size 7 are formed. But if 5 aggregates of size 3 combine with another 5 of size 3, then there are 10 aggregates of size 3 which each combine with an aggregate of size 3, so $A_{33}(t)=10$ whereas only 5 aggregates of size 6 are produced.

The next consideration was those combinations of aggregates which increase the number of aggregates of size i . The combination of an aggregate of size j with one of size k will do so if $j+k=i$. Thus at each time t , $X_i(t)$ is increasing at the rate of the sum of $A_{jk}(t)$ with $j+k=i$. If $j=k$, then the appropriate term is $A_{jj}(t)/2$. In order that each combination be considered only once, the following restriction is added: $j \leq k$; thus $A_{12}(t)$ and $A_{21}(t)$ are not both added to $X_3(t)$.

The combinations of aggregates which decrease $X_i(t)$ are all those of the form $A_{ij}(t)$ subject only to the condition that $i+j \leq N$.

Putting this information together, the following system of differential equations may be written, where $X'_i(t)$ is the rate change of X_i at time t , that is, $dX_i(t)/dt$.

f i is odd, then:

$$X'_i(t) = \sum_{\substack{j < k \\ j+k=i}} A_{jk}(t) - \sum_{i+j \leq N} A_{ij}(t) \quad (1)$$

f i is even, then:

$$X'_i(t) = \sum_{\substack{j < k \\ j+k=i}} A_{jk}(t) + A_{i/2, i/2}(t)/2 - \sum_{i+j \leq N} A_{ij}(t) \quad (2)$$

To complete the model, $A_{ij}(t)$ was derived. The rate of combination of aggregates of size i with aggregates of size j should be proportional, according to the law of mass action, to the product of the concentration of the interacting aggregates. Thus, $A_{ij}(t) = C_{ij} X_i(t) X_j(t)$, where C_{ij} represents the readiness of aggregates of size i to combine with aggregates of size j . It is assumed that C_{ij} is proportional to the product of the average surface area of aggregates of size i and of aggregates of size j , that is $C_{ij} = C s_i s_j$, where s_i and s_j are the average surface of aggregate of size i and j . We thus have:

$$A_{ij}(t) = C s_i s_j X_i(t) X_j(t) \quad (3)$$

Because the shape of the red cell is a non-rigid biconcave disk, a mathematical estimate of the effective surface area of aggregates would be a major undertaking. It was therefore decided to use a physical model consisting of rigid spheres to obtain an approximation of aggregate surface area for small aggregates. Models of different aggregate size, with maximum contact among the spheres, were constructed. The effective surface area of each aggregate was estimated by attempting to fit a free sphere into the aggregate and then tracing around it. The exposed traced areas were cut out and weighed for each model aggregate. Based on the weight of the fragments, the relative effective surface of single spheres and aggregates of sizes between one and nine were calculated (Table 2). For aggregates beyond nine, it was assumed that the aggregates were spherical and the increase in surface was calculated per unit increase in volume. Thus, for sizes greater than nine, surface area was obtained recursively. $s_i = (i/i - 1)^{2/3} s_{i-1}$.

Table 2. THE RELATIVE EFFECTIVE SURFACE AREA OF DIFFERENT SIZE AGGREGATES (I-IX) BASED ON A RIGID SPHERE MODEL

I	II	III	IV	V	VI	VII	VIII	IX
1.00	1.48	1.81	2.07	2.32	2.59	2.88	3.14	3.41

Having obtained values for the surface area of different size aggregates, C of equation (3) remains as a parameter which varies with the aggregating potential of the sensitized cells. This parameter would include any factor which

Fig. 1. A plot of curves representing the concentration of particles with time, substituting different values for C (aggregating potential of cells)

Fig. 2. A comparison of three different theoretical and experimental curves obtained with human anti-A sera and hog A substance coupled to tanned human O cells. The theoretical curves are represented by solid lines and the experimental curves indicated by points. Values of C : 1.1×10^{-5} , 1.6×10^{-5} and 4.0×10^{-5}

affects either the quantitative or qualitative characteristics of the antigen-antibody reactions responsible for agglutination⁶. For example, at different antiserum concentrations the red cells are sensitized to different degrees, altering the rate at which antibody cross-linkages are formed between cells and, therefore, the rate of aggregation. A fit of such different rate curves could be achieved by substituting an appropriate value for C .

The computations required to solve the equations for a theoretical rate curve were performed on an IBM '7094' computer and were obtained by the recursive formula: $X_i(t+1) = X_i(t) + X'_i(t)$, t being in minutes with the boundary conditions that all $X_i(0) = 0$ except for X_1 which equals the initial number of free cells. In these computations, aggregates up to 100 cells in size were allowed. Several theoretical curves of total particle count with different values of C are shown in Fig. 1. At low values of C a nearly linear rate is obtained. With a progressive increase in the value of C there is a decreasing effect on the rate curve. Theoretical curves and experimental curves obtained with different concentrations of antiserum are compared in Fig. 2. It can be seen that the mathematical model does give a reasonably close approximation to the rates of aggregation obtained experimentally.

According to the foregoing considerations, the process of immune aggregation is pictured as a sequence of second-order reactions which can be mathematically expressed as a system of second-degree first-order differential equations with constant coefficients.

RADIOBIOLOGY

Electron Spin Resonance Investigations of Ultra-violet and X-irradiated Homocysteine-thiolactone

SOME time ago we discussed the formation of radicals in irradiated samples of methionine¹ and bovine serum albumin². In the case of methionine, in which the bivalent sulphur is present in the form of a thioether, X-irradiation forms radicals of the alkyl-type, but ultra-violet irradiation (254 mμ) localizes them at the sulphur atom. Moreover, ultra-violet light is able to quench the alkyl-type radicals. In the case of bovine serum albumin, X-irradiation as well as ultra-violet light forms a complex electron spin resonance spectrum consisting of a glycylglycine- and a sulphur-radical³. The portion of the sulphur radical part becomes bigger after ultra-violet irradiation. By ultra-violet irradiation of longer wave-length ($\lambda > 300$ mμ) the X-ray conditioned radical state at the carbon atom is transferred to the SS- or SH-groups of the albumin molecule. In the following investigations we controlled the behaviour of the bivalent sulphur in the form of a thiolactone ring compound, that is, a thioester, homocysteine-thiolactone (HCT):

Polycrystalline, *d,l*-homocysteine-thiolactone (HCT)-HCl (Degussa, Konstanz/Germany) with a bulk volume of about 220 cm³/100 g was sealed under vacuum ($< 10^{-3}$ torr) and irradiated at room temperature. The electron spin resonance measurements were carried out under the same conditions as previously described¹. The X-irradiation was carried out with a 200 kV source (half value layer: 0.64 mm copper, dose-rate 920 r./min, dose 100 kr.). The irradiations with ultra-violet were performed with a mercury low-pressure lamp (NN 15/44, Quarzlampengesellschaft, Hanau, Germany) which emits mainly in the 254 mμ line. The intensity of the ultra-violet irradiation at the sample tube amounted to 9×10^3 ergs cm⁻² sec⁻¹. The other technical details have been reported in a former publication¹.

After X-irradiation a radical yield of 10.8/100 eV is obtained. The electron spin resonance signal of the X-irradiated HCT is demonstrated in Fig. 1 (solid line). Though it is not possible to differentiate the obtained spectrum of the polycrystalline material, it is possible to ascertain that there exists no sulphur radical state. The different behaviour of saturation effects of the micro-wave energy on the different parts of the spectrum includes at

least two different radicals. We suppose that the unpaired electrons are localized at a carbon and/or nitrogen atom of the molecule. The radicals are very stable not only in vacuum but also in air. In vacuum and at room temperature the decay of the radical concentration is only about 1 per cent/h.

In contrast to methionine and bovine serum albumin ultra-violet light of 254 mμ has no influence on the X-ray signal of homocysteine-thiolactone. The dotted line in Fig. 1 shows the change of the X-ray spectrum after an ultra-violet irradiation of 7 h. This dotted line spectrum demonstrates clearly that only one part of the former spectrum is influenced by quenching. The same change is obtained by warming up the X-irradiated sample of HCT. In comparison with the solid line spectrum (X-ray alone) the radical concentration was found to be diminished after ultra-violet irradiation to nearly 88 per cent. It is very interesting that no sulphur radical is detectable although the lactone ring is opened by the ultra-violet irradiation. The latter process is certain because hydrogen sulphide gas is liberated. Perhaps the yield is not big enough to detect the sulphur radicals by the sensitivity of the electron spin resonance spectrometer.

If HCT is irradiated only with ultra-violet light of the wave-length of 254 mμ for 8 h, a radical concentration of only 5 per cent is obtained corresponding to that of an X-irradiation with 100 kr. This ultra-violet signal is not decomposed, it might be a quintet and centred at $g = 2.0046$. In contrast to sulphydryl-, disulphid- and thioether-compounds, there is no sulphur radical to be found for the thiolactone.

The results we obtained from bivalent sulphur containing compounds demonstrate quite clearly that not only the primary formation of sulphur radicals but also the transfer of the radical state to the sulphur atom depends on the chemical binding of the bivalent sulphur. In our next publication we hope to describe the influence the whole molecule has on the character of the sulphur radical.

Use of Technetium-99m in Hepatic Scintillography

HARPER *et al.*¹ have recently pointed out the excellent possibilities of technetium-99m in medical scintillography.

Tc-99m is a nucleid with a period of semidisintegration time of 6 h, emitting γ -radiation of 140 keV, obtained by acid elution of molybdenum-99 adsorbed on an aluminium column. It is obtained as a pertechnetate (TcO_4^-), which has a behaviour similar to the I⁻ ion in the body. We have used it with very good results in thyroid scintillography^{2,3}. Harper has also used this compound combined with a colloid which is retained by the reticulo-endothelium in liver scintillography¹. The Production Department of the Comisión Nacional de Energía Atómica, Argentina⁴, has obtained a colloid of antimony sulphide which has a molecular size of 100 to 400 mμ, an adequate take-up of ^{99m}Tc, and appears to be very stable. We have been able to obtain hepatic pictures of excellent resolution by intravenous injection of this substance (Fig. 1). Its concentration in the liver allows us to perform tracing only 10 min after injection and its activity is still at adequate levels after 180 min.

After 24 h the activity eliminated by urine was 10–15 per cent. We have used activities of 0.4–1.0 mc.

BIOLOGY

Multiple Thymus Grafts in Aged Mice

ONE characteristic of the thymus which has not yet been explained completely is the weight loss (primarily lymphoid depletion) of the organ with increasing age. This process, known as thymus involution, is most marked immediately after puberty, but thymus involution continues, albeit at a slower rate, throughout subsequent life.

The recent data of Harris *et al.*¹ from parabiotic mice and Miller² and Metcalf and Wakonig-Vaartaja³ from thymus grafts have made it evident that the lymphoid population of the thymus is replaced continuously during life by precursor cells seeding in the organ from the blood. These precursor cells then proliferate to build up a large new population of primitive and mature thymic lymphocytes. The most probable source of these thymus-seeding precursor cells is the bone marrow.

Analysis of the growth patterns of thymus grafts has suggested that the growth of the lymphoid elements of the thymus is regulated by the non-lymphoid elements of the organ—the specialized thymic epithelial and reticulum cells⁴. The strength of the proliferative stimulus exerted by these elements appears to decrease with advancing age and, if so, this could be the basis for the decrease in size of the organ with advancing age. However, in view of the continuous replacement of the lymphoid

population of the organ throughout life by precursor cells of extrathymic origin, another possible basis for the decline in size of the organ is that, with advancing age, the supply of thymus-seeding precursor cells becomes restricted, leading to a limitation in the total amount of thymic lymphoid tissue which can be built up, and sustained, by the proliferative activity of these cells.

To investigate the possibility that the supply of thymus-seeding lymphoid precursor cells may be limited in old animals, use was made of an earlier observation that when more than one thymus is grafted to a young recipient, each graft behaves autonomously, achieving the same size it would if grafted alone to a normal or even a thymectomized recipient⁵. This allows the possibility of growing unlimited amounts of thymus tissue in the same animal and thereby of testing whether the supply of thymus-seeding cells ever becomes limiting for the growth of such grafts—particularly in very old animals. In the present investigation, 20-month-old C57 BL mice were each grafted subcutaneously with 12 or 24 whole 1-day-old C57 BL thymus glands. One month after grafting the weights of thymus grafts and host lymphoid organs were determined. As controls, C57 BL thymus glands were grafted to young adult C57 BL mice (either 1, 12, 24 or 48 per recipient) and these grafts were also examined one month after grafting. The results obtained are summarized in Table 1. In agreement with previous investigations⁵, in the young hosts, a linear relationship was observed between the number of thymus glands grafted and the total weight of thymus graft tissue recovered. In neither type of host did the multiple thymus grafts significantly affect the weights or the histological appearance of the host thymus or other lymphoid organs. It is evident that the total mass of thymus graft tissue achieved in 4 weeks in the old recipients was somewhat less than for the corresponding number of grafts in young adult recipients. However, the mass of thymus graft tissue achieved far exceeded that of the maximum size of the normal C57 BL thymus in young mice (60 mg). Histologically no difference between grafts in young and old hosts could be detected in the morphology, extensiveness and mitotic activity of the cortical lymphoid regions of the thymus graft tissue.

Table 1. THYMUS GRAFT WEIGHTS ATTAINED BY MULTIPLE WHOLE C57 BL THYMUS GRAFTS IN YOUNG AND OLD C57 BL MICE

Age of recipient at grafting	No. of thymus glands grafted per recipient*	No. of recipients	Mean host thymus weight (mg)	Mean weight of individual thymus grafts (mg)	Mean total thymus graft weight per recipient (mg)
2 months	1	28	47	24	24
	12	41	42	22	262
	24	2	48	25	609
	48	2	36	24	1,160
20 months	12	18	16	16	185
	24	2	15	19	467

* Mean weight of each donor thymus gland, 3 mg.

Since the lymphoid population of thymus grafts is derived from host cells, it is obvious from the present experiments that, although there may be some restriction in the supply of thymus-seeding precursor cells in old age, the available supply is quite capable of supplying thymus-seeding precursor cells for a mass of thymus tissue far exceeding that of even the pre-involutional thymus. Therefore it may be concluded that no significant limitation in the supply of thymus-seeding precursor cells exists in older mice and such a factor cannot be responsible for the decrease in size of the thymus with advancing age. Recently, Makinodan and Peterson⁶ have demonstrated that in old mice the number of cells in the spleen capable of being stimulated by sheep red cells does decline in old age, and we have obtained similar results in C57 BL mice. The cell population in the spleen is replaced continuously by cells entering from the blood in essentially the same manner as is that in the adult thymus. It appears therefore that although the supply of some spleen-seeding cells may become restricted in old age, there is no significant

limitation in the supply of thymus-seeding cells in mice of a similar age.

Role of Sialic Acid in Potassium Transport of L1210 Leukaemia Cells

THE cell membranes of various tumour strains possess large quantities of sialic acid and a strong, negative surface charge¹⁻³. This charge, which is partly due to the ionized carboxyl group of sialic acid^{2,4,5}, may be important in influencing physiological properties such as transport of ions⁶. Since tumour cells seem to concentrate K⁺ ions better than normal cells⁷⁻⁹, we have begun to investigate the regulation of K⁺ fluxes by sialic acid.

L1210 mouse leukaemia cells, which had been maintained in the ascitic form, were washed at 3° C with isotonic saline until free of red blood cells. The L1210 cells were then incubated for 90 min at 37° C in the incubation media shown in Table 1. Sialic acid was removed from the leukaemia cells by the addition of neuraminidase (*Vibrio cholerae*), which was present at a final concentration of 50 units/ml. Under these conditions the sialic acid released is derived essentially from the cell membrane⁴. Free sialic acid was determined by the method of Warren¹⁰. Na⁺ and K⁺ ions were assayed by means of a flame spectrophotometer. The optimum wave-lengths were 589 mμ for Na⁺ and 766.5 mμ for K⁺. ¹⁴C-D-Glucose (5.2 × 10³ c.p.m./μmole) and ¹⁴C-L-lysine (1.6 × 10⁵ c.p.m./μmole) were utilized in measuring glucose and lysine uptakes.

Table 1. CONSTITUENTS OF THE INCUBATION MEDIA

Substance	Conc. (mM)	K-free	Incubation medium K-low _g	K-free _{g-1}	K-low _{g-1}
L-Lysine	0.2	—	—	+	+
D-Glucose	4.9	—	+	+	+
KCl	10.0	—	+	—	+
NaCl	130.2	—	+	—	+
NaCl	140.2	+	+	—	—
Na ₂ HPO ₄	4.8	+	+	+	+
NaH ₂ PO ₄	5.2	+	+	+	+
CaCl ₂	0.9	+	+	+	+
CH ₃ COONa	5.0	+	+	+	+

The amounts of sialic acid removed by neuraminidase in the K-free medium were 0.21 μmole/100 mg dry wt of cells after 45 min of incubation and 0.23 μmole/100 mg dry wt at 90 min. The quantities of sialic acid released were nearly the same in any of the incubation media listed in Table 1, and the values obtained approximated those determined for the Ehrlich ascites tumour cell⁴.

Different incubation media were utilized in the transport investigations, so that the direction of ion flow could be altered. In the K-free medium, K⁺ release from the L1210 cells accompanied Na⁺ uptake; with the K-low_g medium, K⁺ uptake accompanied Na⁺ release. Table 2 includes the results of typical experiments, in which the removal of sialic acid inhibited K⁺ transport, regardless of direction of flow. When the results from a number of experiments were pooled, the differences between the control and the experimental groups were found to be statistically significant (*P* < 0.05). Contrary to the relatively sharp response of K⁺ ions to the removal of sialic acid, Na⁺ transport was only slightly inhibited when neuraminidase was present, and in this case the results did not yield significant differences.

Table 2. TRANSPORT IN L1210 CELLS STRIPPED OF SIALIC ACID

Medium	Substance measured	Time (min)	μmoles/100 mg dry wt. of cell	Control	+ Neuraminidase
K-free	K ⁺	45	—	-2.56	-1.97 (23)
		90	—	-4.60	-3.40 (26)
	Na ⁺	45	—	+15.1	+13.4 (11)
		90	—	+13.8	+12.0 (13)
K-low _g	K ⁺	45	—	+25.0	+16.0 (36)
		90	—	+26.0	+17.0 (35)
	Na ⁺	45	—	-50.0	-45.0 (10)
		90	—	+3.13	+3.09 (1)
K-free _{g-1}	D-glucose	45	—	+6.31	+6.25 (1)
		90	—	+0.208	+0.204 (2)
	L-lysine	45	—	+0.206	+0.207 (0)
		90	—	—	—

(+) Indicates flow into the cells; (−) indicates flow out of the cells. Percentage decreases from the control values are given in parentheses.

Glucose uptake was determined for both the control cells and the enzyme-treated cells and did not appear to differ between the two groups. This finding suggests that transport in general was not affected by sialic acid and that K⁺ transport in particular was not regulated by the action of membrane-bound sialic acid on glucose utilization. Furthermore, although glucose was absorbed from the K-free medium, the removal of sialic acid inhibited K⁺ outflow.

Finally, sialic acid was found not to affect lysine uptake in the absence or presence of K⁺ ions, thereby indicating that sialic acid does not influence transport of positively charged substances in general.

Pardee¹¹ has postulated that altered surface properties of tumour cells may cause a loss of growth control mechanisms. The accumulation of K⁺ ions in malignant cells⁷⁻⁹ may well be such a mechanism, which is partly responsible for the adaptation of these cells to a state of uncontrolled growth. The presence of K⁺ ions is necessary for optimal growth of certain bacteria strains^{12,13} and plant tumours^{14,15}. Lubin¹⁶ has demonstrated a control of protein synthesis by K⁺ accumulation. The work recorded here in turn indicates that sialic acid apparently mediates both the inward and outward diffusion of K⁺ ions in a leukaemia cell.

We thank Prof. Arthur B. Pardee for his advice. This work was supported by grants 1-F2-CA-24245-01 and AI-04409 from the U.S. Public Health Service.

Occurrence of Fructose-1-phosphate in Tissues of Higher Plants

THERE is considerable evidence for a role of fructose-1-phosphate in the metabolism of some animal tissues¹. Relatively little is known about the occurrence of this compound in higher plants. Cardini² has shown that preparations of jack bean seeds can cleave fructose-1-phosphate to dihydroxyacetone phosphate and a compound which is probably glyceraldehyde. On the basis of electrophoretic separation, Schwimmer, Bevenue and Weston^{3,4} tentatively identified fructose-1-phosphate in extracts of potatoes. We report here evidence for the

presence of fructose-1-phosphate in storage tissue of carrot (*Daucus carota* L.) and white turnip (*Brassica rapa* ssp. *rapa*).

Disks (1 mm × 10 mm) of the tissues were aerated at 25° C for 17 h in distilled water and then in 0.1 mM KH_2PO_4 for a further 24 h. The tissue was rinsed and extracted successively with boiling 80 per cent ethanol, 20 per cent ethanol and water. The phosphate esters in the combined extracts were fractionated by ion-exchange resin column chromatography using a technique⁵ similar to that of Bartlett⁶. The hexose monophosphates, free from hexose diphosphates, were located by their radioactivity, by reaction with anthrone reagent (for hexoses)⁷ and by a slightly modified cysteine-carbazole reaction (for fructose)⁸. Fractions containing mainly fructose phosphates were subjected to one-dimensional paper chromatography in each of two solvents. Solvent 1 was ethyl acetate-glacial acetic acid-water, 3 : 3 : 1 by volume⁸, and was used with Whatman No. 1 paper. Solvent 2 was *tert.*-butyl alcohol-0.1 N hydrochloric acid, 80:20, v/v (ref. 9), and was used with Whatman No. 4 paper. These solvents separated glucose-1- and glucose-6-phosphates from fructose-1- and fructose-6-phosphates and also gave a partial separation of the two fructose phosphates. Although the separation of fructose phosphates on paper chromatograms was not complete, it was sufficient to enable the two compounds to be distinguished by their characteristic ultra-violet fluorescent reactions as described below.

These procedures revealed the presence of a compound in carrot and turnip extracts which behaved similarly to authentic fructose-1-phosphate. The results in Table 1 compare the P constants:

$$\left\{ \frac{\text{distance travelled by compound}}{\text{distance travelled by orthophosphate}} \times 100 \right\}$$

of the extracted compounds with the P constants of authentic fructose-1- and fructose-6-phosphates and those of other sugar phosphates which could have been components of the eluates obtained from ion-exchange resin column chromatography.

Table 1. P CONSTANTS AND ULTRA-VIOLET FLUORESCENT REACTION WITH GLYCEROL/HCl/ACETONE REAGENT OF SOME CARBOHYDRATE PHOSPHATES COMPARED WITH COMPOUNDS ISOLATED FROM CARROT AND WHITE TURNIP

	P constants Solvent 1	Solvent 2	Ultra-violet fluorescent reactions in each solvent
F-1-P	63	73	yellow
F-6-P	66	81	red-brown
G-1-P	52	67	none
G-6-P	47	67	none
R-5-P	75	92	none
P _i	100	100	none
Carrot	62	75	yellow
	67	82	red-brown
Turnip	62	74	yellow
	67	82	red-brown

Evidence that the compound obtained from carrot and turnip was fructose-1-phosphate was obtained by a modification of the technique of Steinitz⁹. Under our conditions in which the reagent was sprayed onto the chromatogram, authentic fructose-1-phosphate gave an intense yellow fluorescence and authentic fructose-6-phosphate a dull, red-brown fluorescence which changed to yellow on heating for a further 3-4 min. The ultra-violet fluorescent reactions of the isolated compounds obtained under a 'Chromatolite' (Hanovia Lamps, Slough, England) were compared with those of authentic samples of fructose phosphates and other sugar phosphates likely to be present in the column eluate fractions (Table 1). Subsequent development of the chromatograms with the reagent of Hanes and Isherwood¹⁰, as modified by Bandurski and Axelrod¹¹, confirmed that the isolated compounds contained phosphate.

Additional evidence that the plant extracts contained fructose-1-phosphate was provided by the demonstration

that column eluate fractions, suspected of containing fructose-1-phosphate, contained a substrate for an aldolase preparation isolated from rat liver by the method of Leuthardt and Wolf¹². This preparation, which is known to cleave both fructose-1,6-diphosphate and fructose-1-phosphate, was used to assay the column eluate fractions for fructose-1-phosphate by linking the production of dihydroxyacetone phosphate to the oxidation of NADH, on the addition of purified α -glycerophosphate dehydrogenase. Values of 1.95 and 2.11 μ moles of fructose-1-phosphate/100 g fresh weight were obtained for carrot and turnip tissue respectively.

Some Postulated Relationships among Autumn Phenomena in Woody Plants

Most research on winter hardiness (cold acclimation) of plants has been concerned with changes in amounts of organic compounds such as sugars, amino-acids and proteins. These autumnal alterations in organic constituents of the cell can only be brought about by changes in enzymes. The question as to what initial factor causes this change in the metabolism is still not solved. It is tempting to think of a hormone action which could influence a great many enzyme systems¹, especially since cold acclimation and de-acclimation are closely associated with the growth-regulator controlled phenomenon of growth cessation in autumn, and growth resumption in spring. Recently, Levitt² has suggested that protein and glutathione sulphydryls bear a direct relationship to the state of winter hardiness of plants. Sulphydryl groups in cells are essential for the three-dimensional structure of cell proteins³ and for cell growth⁴. Glutathione is also an essential part of the ascorbic acid oxidase system which is involved in growth processes, that is, ascorbic acid oxidizing capacity is low in growing plants and high in dormant plants. Marré and Arrigoni⁵ presented evidence that auxins inhibited the ascorbic acid oxidase and thereby increased the ratio of reduced to oxidized glutathione. A postulated relationship between ascorbic acid oxidase and glutathione can be represented as follows:

AH₂, metabolic substrate; G-S-S-G, oxidized glutathione; GSH, reduced glutathione; AA, ascorbic acid; DHA, dehydroascorbic acid.

It has also been found⁶ that there is a shift in wheat caryopses from the cytochrome oxidase system to the ascorbic acid oxidase system after cold treatment. An increase in glutathione oxidizing activity, along with an apparent rise in ascorbic acid oxidizing activity, was observed in cold acclimating plants⁷. This high rate of

ascorbic acid oxidizing activity is contrary to the low capacity in vigorously growing tissue and thus must be due to an absence or inhibition of growth-promoting substances in cold treated tissue.

It has been reported by several investigators^{8,9} that the biosynthesis of growth promoters in woody plants levels off during the growing season, and that the concentration of growth inhibitors increases toward autumn. It has also been reported that there was a significant increase of tryptophan in dormant tissue after low-temperature treatment¹⁰. As tryptophan is considered to be the precursor of indolyl-3-acetic acid¹¹ its accumulation would suggest an arrest of auxin synthesis. An actual decrease of auxin has been reported to occur in cold-acclimated plants¹².

Changes in growth regulators may influence many processes. It has been reported that they are able to affect the bioelectric potential of the plant¹³ and thereby may change the cell membrane permeability¹⁴ which is a prerequisite for the cold acclimation process¹⁵. They may also affect the properties of proteins¹⁶ as well as the enzyme action already mentioned.

Growth inhibitors may affect the hardiness process as the synthetic growth inhibitor maleic hydrazide does¹⁷, via the sulphydryl groups of the mitotic cell¹⁸. Several natural growth inhibitors have been reported to occur¹⁹; many are flavonoid-like structures^{20,21}; others, such as β -inhibitor²², have only been tentatively identified²³. Flavonoids have been known to influence plant metabolism in several ways²⁴.

The phenomena in red-osier dogwood during autumn occur in the following order²⁵: irreversible rest inducement, cold acclimation, and loss of rest. The sequence of this process could be in these steps. An inducement of rest is brought about by some kind of phytochrome system²⁶. At this time, a hormone is produced which causes an increase in RNA content²⁷ and a subsequent increase of water-soluble proteins. Although the nature of these water-soluble proteins is obscure, some of them may represent an increase of enzymes which are responsible for the increase of carbohydrates and other organic products in cold acclimating plants.

Freeze-fixation, a New Method for Electron Microscopy

FREEZE-FIXATION implies rapid freezing of small specimens followed by vapour fixation at a low temperature. This method differs from freeze-drying by not removing the water of the specimen before fixation, and from the freeze-substitution by not replacing the water during fixation. All these three methods work with frozen tissue, but since the mode of fixation varies the ultrastructure of the cellular constituents also varies. Therefore, further information of the cellular constituents might be obtained.

For freezing, small specimens are rapidly frozen in liquid nitrogen according to the usual technique for freeze-drying. The frozen specimens are collected in a small weighing bottle with grounded stopper. The bottle contains a substance suitable for vapour fixation and serves as a fixation chamber after freezing.

For fixation, the bottle containing specimens and fixation substance, and filled with liquid nitrogen, is placed in dry ice. At this temperature, the liquid nitrogen evaporates. The bottle is then firmly closed with its stopper and left in a freezer for 2-3 weeks for vapour fixation. The only fixation substance as yet tried in the experiment is crystalline osmium tetroxide. After the period in dry ice, the specimens are either left in the bottle for further fixation at room temperature or brought to the appropriate solution of the embedding chemicals used. In the present experiments, plastic embedding has been started in 70 per cent ethanol for the 'Epon' procedure or 25 per cent component 'A' of the 'Durcupan' procedure.

The main drawbacks of freeze-fixation are the low vapour pressure of the fixation substance at -30°C and the slow penetration of the fixative into the frozen tissue. The specimens therefore must be small, preferably single cells. The morphological quality of the tissue is inferior to that obtained after freeze-drying. Thus, the several artefacts impede investigations of the whole cell, but they do permit analysis of, for example, the cell membrane.

MICROBIOLOGY

Endogenous Bud Formation in the Hypotrichida

As a general rule, ciliated protozoans reproduce asexually by transverse binary fission. Suctorians, however, characteristically produce unequal endogenous buds which develop into migratory ciliated larval forms. Endogenous budding has not been reported in the remaining subclasses of the Ciliata. Observations made by Kent suggest that one member of the Hypotrichida has a larval stage in its life-cycle¹. He observed the development of an embryonic hypotrich, which closely resembled *Glaucoma margaritaceum* Ehr., into *Aspidisca costata* Ehr. In the same treatise Kent considers the holotrich genera *Glaucoma* and *Microthorax* to be embryonic or transitional phases in the life-cycles of higher hypotrichous forms. No other reference to such life-cycles in the Hypotrichida have been found.

This communication presents preliminary observations made on monoxenic clonal cultures of the hypotrichous ciliate *Histriculus vorax* Corliss. *Bacillus cereus* was used as the sole food organism, and the ciliate culture was originally separated from activated sludge.

Fig. 1. Size frequency curve showing the presence of two distinct adult cell sizes within a well-fed clonal population of *Histriculus vorax*

Great variations in size have been noted in clonal populations, but 70 per cent of the cells in such populations fall within two definite ranges of size (Fig. 1). Large adult cells (190–220 μ long, 80–100 μ wide) are bluntly shaped, whereas small adult cells (100–140 μ long, 50–60 μ wide) are streamlined in their appearance. Both adult forms are capable of normal transverse division resulting in the production of two daughter cells the dimensions of which, after a short period of growth, resemble those of the mother-cell. The large adult cells form 20–30 per cent of a well-fed clonal population, but under conditions of starvation they are absent.

Observation has shown that the large adult cells (Fig. 2) develop endogenous bi-macronucleate buds (20–40 μ diameter) which, when mature, are extruded through the cell wall. After extrusion, the mother-cell may either then produce more buds endogenously or divide transversely. Newly deposited buds may either develop directly into a ciliated larval form or, if conditions are unfavourable, the bud will encyst.

Fig. 2. Formation of endogenous buds in *Histriculus vorax* Corliss. a, Large adult containing two developing endogenous buds; b, large adult mother-cell containing a mature endogenous bud

Isolated encysted buds have been excysted by placing them into fresh culture media. Excystment takes approximately 48 h to complete at room temperatures, and terminates when a non-trophic migratory larval form, which bears only caudal and frontal cirri, emerges (Fig. 3). Under favourable conditions newly deposited buds develop directly into larval forms which cannot be distinguished from the embryos which emerge from encysted buds. The non-trophic embryos rapidly develop feeding membranelles and a full adult complement of cirri. The trophic larval stage grows and quickly develops into a small adult capable of transverse binary fission.

Variation of the X-ray Sensitivity of *Serratia marcescens* with Relative Humidity

In a recent article¹ describing the effects of humidity on the inactivation of micro-organisms, the results of some preliminary experiments with X-rays were presented. The present communication reports an extension of this work in which the effect of atmospheric oxygen in modifying the radiation sensitivity at various humidities was investigated in addition to the protective effect of inositol. Inositol was of particular interest because of its apparent ability to replace water in biologically important macromolecules² and in this way to protect cells against inactivation by drying, ultra-violet and X-rays^{1,3}.

The effect of inositol appears to be similar to that of glycerol, which has been the subject of a number of recent investigations^{4–10}. The role of water in the radiation inactivation of bacterial spores and vegetative bacteria has been extensively studied by Powers and his colleagues^{6,7,11,12}.

For the experiments reported here, a sub-culture of *Serratia marcescens* was prepared by incubation in heart infusion broth for 48 h. Cells from the culture were centrifuged, washed, and re-suspended in either distilled water or a 5 per cent (0.3 M) solution of meso-inositol. One ml. samples from the foregoing suspensions containing about 5×10^9 cells were deposited on 'Millipore' filters. The filters were placed in an irradiation chamber through which air or nitrogen of the desired relative humidity could be passed. The relative humidity of the gas which had passed over the filters was measured with a membrane-type meter ('Serdex'). The meter reading was dependent not

only on the relative humidity of the gas entering the irradiation chamber, but also on the degree to which the cells had come into equilibrium with the relative humidity of this gas. For experiments with a nitrogen atmosphere, commercial nitrogen (oxygen concentration less than 70 parts per million) was passed through the irradiation chamber for at least 1 h before beginning the irradiations.

After equilibration, cells were irradiated with unfiltered 200 kVp. X-rays (half-value thickness, 8 mm aluminium) at an exposure rate of 790 r./min. The irradiations were carried out at room temperature (22°C–25°C). In some experiments, cells were irradiated in suspension after aeration of the suspension by bubbling air through it. After irradiation, the cells were plated on heart infusion agar. Visible colonies were scored after 24 h incubation at 35°C.

The survival curves obtained under all experimental conditions appeared to be exponential and were fitted by an expression of the form $N/N_0 = \exp(-kD)$, where N and N_0 are the number of colony-producing cells in the irradiated samples and the unirradiated control, respectively, D is the absorbed dose and k is an inactivation constant, which was used as an index of radiation sensitivity under the various conditions. In the control samples it was found that 30–50 per cent of the cells deposited on the filter would later produce colonies even after storage at a relative humidity as low as 25 per cent for several hours.

Values obtained for the inactivation constant for *Serratia marcescens* irradiated in air are shown in Fig. 1. The relative humidity values on the abscissa scale refer to the atmosphere above the cells. The circles and upper curve give values for k obtained for cells deposited from a water suspension, the triangles and the lower curve for cells deposited from a 5 per cent inositol solution. It may be seen that inositol has a protective effect at all relative humidities and that this protection is nearly constant at humidities below 70 per cent. This is in contrast to the results for ultra-violet irradiation of cells in aerosols in which a marked increase in the protective effect of inositol with decreasing relative humidity was found¹. The abrupt decrease in sensitivity at a relative humidity of about 80 per cent in both the curves shown in Fig. 1 is believed to be due to the removal of 'free' water from the cell and therefore to a decrease in the 'indirect' effect produced by the radiolysis of water.

This decrease is in contrast to the results of Tallentire and Powers¹² for the bacterial spores and those of Webb⁸ for vegetative cells of *Staphylococcus aureus*. These workers observe an increase in sensitivity with decreasing water vapour pressure if oxygen is present during and after the irradiation. The difference may be due to differences in the procedure by which the cells are dried.

Fig. 1. X-ray sensitivity of *Serratia marcescens* cells irradiated under an atmosphere of air, having previously been suspended in water (○) or in 5 per cent inositol (Δ).

Fig. 2. X-ray sensitivity of *Serratia marcescens* under various conditions indicated. ○, Water-air; ●, water-nitrogen; ▲, inositol-nitrogen.

In Fig. 1 the shape of the curves below 70 per cent is consistent with a model in which the inactivation constant is assumed to have two components one of which, k_0 , is independent of water in the cell and the other, k_1 , is proportional to the amount of water which has been removed by drying, taking the amount of water at various relative humidities from data measured by Webb⁸. The increase in k_1 with decreasing humidity does not appear to correspond directly to the much greater increase observed by Powers and his colleagues for bacteria and spores irradiated and stored in the presence of oxygen^{8,12}.

The measured inactivation constants for cells irradiated under a nitrogen atmosphere are shown in Fig. 2. The water-air curve from Fig. 1 has been included in Fig. 2 to facilitate comparison. For cells deposited from a water suspension and irradiated at high humidities (above 80 per cent) there is a marked decrease in sensitivity when air is replaced by nitrogen. This 'oxygen effect' nearly disappears at a relative humidity of about 70 per cent, suggesting that the damage due to the 'indirect' effect, postulated here, requires the presence of oxygen. Below 70 per cent the inactivation constant for cells irradiated in air increases with decreasing relative humidity whereas that for cells irradiated in nitrogen appears to remain nearly constant. It therefore appears that the inactivation described by k_1 , which we have associated with the amount of water in the cell, requires the presence of oxygen. The humidity-independent component, k_0 , appears also to be independent of oxygen and therefore to correspond to the Class I damage described by Powers and his colleagues^{8,11,12}.

The triangles and the lowest curve in Fig. 2 give the inactivation constants for cells deposited from an inositol suspension and irradiated in nitrogen. These points fall considerably below those for cells deposited from a water suspension and irradiated in nitrogen. The fact that there is a considerable protective effect in the absence of oxygen indicates that the action of inositol is not simply in interfering with oxygen concentration in the cell. Below 70 per cent relative humidity the inactivation constant for inositol-treated cells irradiated in nitrogen is nearly independent of relative humidity and has a value approximately equal to the minimum value for inositol-treated cells irradiated in air. It therefore appears that at the lower humidities there are two kinds of radiation damage both in inositol-treated cells and in unprotected cells, with the humidity-dependent component in each case requiring the presence of oxygen.

These experiments indicate that, at the lower humidities, inositol exerts most of its protective effect by reducing the oxygen-independent component of the radiation damage. This is in contrast to the observed protection by glycerol of cells in suspension which is considerably greater in the presence of oxygen than in its absence^{7,9,10}.

VIROLOGY

Influence of Heavy Water (Deuterium Oxide) on Plaque Size of Western Equine Encephalitis Virus

THE influence of deuterium oxide (D_2O) on virus replication in tissue culture cells is variable. When poliomyelitis virus (a small, RNA virus) is grown in 20–30 per cent D_2O its proliferation is enhanced^{1–3}, whereas simian virus 40 (a DNA virus) does not replicate as well in deuterated medium as it does in protonated medium⁴. In an attempt to ascertain whether the size of a virus or its nucleic acid composition may be correlated with the D_2O effect, we have examined the effects on the replication of western equine encephalitis (WEE), a relatively large, RNA-containing virus.

The influence of 25 per cent D_2O on the replication of two mutants of WEE was studied. The two mutants are distinguished by the size of the plaques which they yield when grown on chick embryo fibroblasts. The method of growing the virus was essentially that of Wecker and Schonne⁵. Fibroblasts of ten-day-old chick embryos were cultivated in 100-mm Petri dishes in a growth medium consisting of Eagle's medium in Earle's balanced salt solution and 10 per cent calf serum. The WEE virus was diluted in Hanks's salt solution and 0.2 ml. of the diluted WEE was added to each monolayer. Virus absorption was permitted to proceed for 1 h at 37° C, then the cells were overlaid with nutrient agar (12 ml. of 1 per cent agar in Eagle-Earle's medium containing 10 per cent calf serum). Half the fibroblast monolayers were overlaid with nutrient agar made up in medium containing 25 per cent D_2O . After 3 days of incubation in an atmosphere of 4 per cent carbon dioxide in air, the plaques caused by the WEE virus were counted and measured. The results of two experiments are presented in Table 1. In every case plaque size was smaller in the D_2O medium. The observed differences are highly significant ($P < 0.001$).

The data presented here indicate that the nucleic acid moiety of a virus does not necessarily determine the nature of the viral growth response in D_2O . To further

CYTOLOGY

Barr Bodies in the Mouse

UP to the present, sex chromatin has not been identified in the nuclei of mouse cells. This is probably due to the fact that such nuclei contain multiple chromocentres, of varying size and number, the presence of which tends to mask the appearance of a sex-specific chromatin mass in females. Moore and Barr¹, in a systematic survey of the nerve cell nuclei of many different mammals, were unable to demonstrate sexual dimorphism in those of the mouse. Later, Hay², examining twenty non-nervous tissues of the mouse, could not identify sex chromatin in any of them. Himrichsen and Gothe³ analysed the multiple chromocentres of murine Purkinje cells, organizing them into eleven arbitrary patterns in accord with their sizes and distribution. Among these patterns there were two configurations with respect to which male and female mice seemed to differ, but neither of these was that of the single nucleolar satellite common to the neurones of female mammals.

A search for peripheral sex chromatin masses—Barr bodies—was made in nuclei of fibroblasts which had grown out from small fragments of mouse peritoneum explanted on to cover slips. This method provided a population of young cells with flattened nuclei which were in a monolayer. Six-week-old male and female CBA/C57BL mice were killed by stunning and neck fracture. Small (2 mm) pieces of peritoneum were excised and placed on cover slips mounted on agar drops in a Petri dish. Each explant was allowed to become adherent in a thin clot which formed spontaneously. The explants were covered with a medium composed of NCTC-109 and foetal calf serum (4:1), and were incubated at 37° C in an atmosphere of 5 per cent carbon dioxide in air. Outgrowth was generally visible on the fourth day, and on the sixth day the tissue fragments were carefully picked off the cover slips, leaving behind a corona of fibroblasts. These were fixed in 95 per cent ethanol, hydrolysed in 1 N hydrochloric acid for 10 min at 60° C, stained in a standardized Feulgen stain for 1 h, dehydrated and mounted in 'XAM' for examination at times 900 under oil immersion using a Wratten B green filter.

In order to avoid the problem presented by the multiple chromocentres (Fig. 1) it was decided to search for Barr bodies only in those nuclei which contained either no chromocentres at all, or the chromocentres of which were sufficiently small so as not to be confused with a Barr body. Such nuclei were designated 'clear' (Fig. 2). To be identified as a Barr body a chromatin mass had to be large (about 1 μ), compact, well defined, and tangent to the nuclear membrane all along its base. The aspect of it which faced inward on the cell was allowed to vary from

a short to a tall pyramid, or to be convex (Figs. 3 and 4). Rectangular masses and masses only slightly tangent to the nuclear membrane were not accepted. All nuclei were examined throughout their volumes.

A preliminary examination of many cover-slip specimens from both male and female animals in accord with these criteria revealed that there was a readily recognizable proportion of female cell nuclei which contained Barr bodies. The corresponding clear nuclei of male cells, on the other hand, did not contain any. These findings were tested further by a review of a series of 'unknown' specimens. Nine mounts were examined independently by two observers who did not know the sex of a given specimen of cells or how many specimens of each sex had been selected for review. Both observers were able readily to identify the sexes of the cell populations. Because subjective factors were numerous it was not felt possible to state exactly the percentage of female nuclei which contained Barr bodies; but after lengthy counts it seemed that about 10 per cent of the clear nuclei contained them. The proportion of nuclei which had to be rejected because of their chromocentre content varied from one preparation to another. In general, somewhat more than half of them were inappropriate for the identification of sex chromatin.

These findings complement the description by Ohno and Hauschka⁴ of a heteropycnotic X chromosome in late prophase in normal and tumorous mouse tissues, and the recent identifications of a late labelling X chromosome in tissue culture of mouse embryo by Galton and Holt⁵ and in the living adult mouse by Evans, Ford, Lyon and Gray⁶. It is recognized that the occurrence of Barr bodies in only 10 per cent of fibroblast nuclei is low as compared with the incidence in tissue cultures from other mammals. This seems due in part to the unavoidable loss of some Barr bodies by disregarding all nuclei which bore chromocentres. By the same token it may be related to the low incidence of late-labelling X chromosomes reported by Evans and his colleagues, for the recognition of a late-labelling X must have been difficult in the presence of the proximal portions of autosomes which labelled equally late. Ohno and Hauschka⁴ have suggested that the

chromocentres of mouse cell nuclei represent allocyely portions of many or all the chromosomes of the complement. The variable size of the chromocentres could be attributed to fusion of some of these heterochromatin regions. The 10 per cent of clear nuclei which we have observed to contain Barr bodies may be those of a proportion of cells in which allocyely of one X is out of phase with allocyely of the remainder of the chromosomes.

We thank Prof. H. Grüneberg for providing the micrograph used in the study. One of us (J. D. K.) was supported by the U.S. Public Health Service as an indirect trainee of the National Institutes of Health.

Electron Microscope Observations of Neurosecretory Elements in the Neurointermediate Lobe in Skates

In this report, observations of ultrastructural organization of neurosecretory elements of the neurointermediate lobe in two types of the Black Sea skates, *Raja clavata* and *Trygon pastinaca*, are considered. As was shown in our earlier work with the light microscope¹, the axoadena neurosecretory contacts in these types of skates are well developed and very distinct. In the literature there appears to be only one report² in which the axoadena contacts with the adenohypophysis elements in *Scyliorhinus caniculus* (L) were examined with the electron microscope, and some other work done on teleosts³⁻⁵.

With the light microscope, it was found that bundles of the neurosecretory fibres were between the strands of the epithelial glandular cells of the intermediate lobe and elements of connective tissue, and vessels were not found in these spaces. The terminal branches of the neurosecretory fibres are found among the epithelial cells, but never reach the sinusoid capillaries located in the epithelial strands. Numerous swellings of the neurosecretory fibres make intimate contact with the glandular epithelial cells.

During investigations with the electron microscope two kinds of unmyelinated nerve fibres—fibres with elementary neurosecretory granules and those without them—were found in the tissue of the neurointermediate lobe.

The terminal swellings of the neurosecretory fibres—neurosecretory endings—have diameters of considerable size (1.5–2.5 μ , more seldom 4–5 μ) as compared with the fibres. Neurosecretory granules with various ultra-thin structure and tiny vesicles (diam., 350–500 Å), resembling 'synaptic' vesicles in typical nerve endings, and also mitochondria are found in the terminal swellings in skates as in all other vertebrates, the mitochondria having various but often irregularly curved shapes.

Three main types of neurosecretory granules are observed in the neurosecretory endings (Figs. 1 and 2): (1) Typical elementary granules ranging from 1100 to 2800 Å. (2) Granules of the same size with their central substance having smaller electron density (the degree varying from one granule to another). The distinctness of the light space between the membrane and the central substance is reduced with the osmophilicity of the central substance of granules.

(3) 'Residual' neurosecretory granules, as we call them⁶, are usually of the same size, but they have membranes which are practically only lipoprotein and are free of the electron-dense central substance. In their structure they resemble vesicles. In some cases, however, we observed the 'residual' granules which are considerably smaller than

mentary granules. Tiny 'residual' granules are almost of same size as the 'synaptic' vesicles of the neurosecretory endings.

Between all three types of the neurosecretory granules there are connecting transitional forms which, as is considered in the literature, demonstrate the process of solving or diluting the substance of a granule during the process of secreting the biologically active substance of the neurosecretory material.

Single neuroglial cells of an elongated form—pituicytes are found among the neurosecretory fibres (Fig. 2). They are poor in cytoplasm, which surrounds the nucleus only as a thin border (100–300 m μ) and turns into relatively thin branches at its poles. It is in these parts of the cytoplasm that the substantial mass of small mitochondria, in canals of endoplasmic reticulum and ribosomes, is concentrated.

The nuclei of pituicytes always have an elongated form—some invaginations often are found on their surface. The nuclei are characterized by a considerable electron density—they contain a large number of chromatin grains. The nucleolus is, as a rule, of a rounded or an oval form and is characterized by high electron density.

Fig. 1. The contact of two neurosecretory endings with a glandular epithelial cell (GC) from the neurointermediate lobe of the hypophysis of *Trygon pastinaca*. Plasma membranes of the terminals and of the glandular cell are divided by a narrow intercellular space about 150 Å. ($\times 37,500$)

ng, neurosecretory granules; rng, 'residual' neurosecretory granules; sv, synaptic vesicles

Fig. 2. The contact of the neurosecretory terminal (NT) with a pituicyte from a neurointermediate lobe of the hypophysis of *Raja clavata*. ($\times 18,000$)

Pituicytes come into close contact with the neurosecretory fibres and sometimes with their terminals. Fig. 2 shows the closest form of such contact where the neurosecretory terminal seems to be invaginated into the body of the pituicytes—the nucleus at the same time being deformed and resembling the invagination form. In their morphology, the pituicytes of skates resemble the oligopituicytes of white mice⁷.

The neurosecretory endings are surrounded by glandular cells on all sides. Their plasma membranes are divided only by a thin slit about 150 Å. Some invaginations are found on the surface of glandular cells at the points of contact. No peculiarities have been observed in ultrastructural organization of bounding membrane and organization of glandular cells in the region of contact with the neurosecretory endings. Compared with typical nerve endings, in the neurosecretory endings there is no concentration of 'synaptic' vesicles near plasmatic membranes which come into direct contact with the surface of a glandular cell. Moreover, no swellings of these sections of membranes similar to those of the presynaptic membrane of typical nerve endings are found.

The foregoing findings concerning the ultrastructure of the neurosecretory endings and the places of contact with the glandular cells testify, we believe, the opinion that the biologically active substances of the neurosecretory granules have a direct influence on the functional activity of the glandular cells of the intermediate lobe. The absence of morphological evidence showing that the neurosecretory granules directly penetrate beyond the endings supports the generally accepted opinion that the biologically active substances of the neurosecretory material—neurohormones—are secreted not as entire granules but as small molecular components.

Interspecific Karyotypic Variation as a Systematic Character in the Genus *Anolis* (Sauria: Iguanidae)

THE examination of animal chromosomes has recently gained impetus from the development of techniques for the short-term culture of blood¹. Modifications of this technique have been used successfully on several species of reptiles².

Most of the classical literature on reptile chromosomes indicates a conservativeness of karyotype at the familial or super-familial level³. Subsequent work by Matthey⁴ on the chamaeleontids indicates that in that family the differences in karyotype can be used to help establish species groups.

Using a technique of whole blood tissue culture utilizing only 2–3 drops of blood⁵ I have made a preliminary examination of the chromosomes of nine species of *Anolis* lizards in order to assess the value of the karyotype as an additional systematic character.

The genus *Anolis* is taxonomically complex, consisting of approximately 200 species, distributed from South America to Central America and Mexico; and throughout the West Indies and the south-eastern United States. On the basis of differences in the structure of the caudal vertebrae, the genus has recently been divided by Etheridge⁶ into two major groups (termed α and β) and

both these groups have been sub-divided into major series of species.

The chromosomes of many reptile species fall into two sharply defined size classes termed macro- and micro-chromosomes³. Here only the macrochromosomes will be discussed, for my chromosome spreads of *Anolis* so far give equivocal results for the smaller elements, some of which may be masked by the arms of the larger elements.

The chromosome spreads obtained from blood cultures indicate that *A. carolinensis* (from Louisiana), *A. equestris* (Cuba), *A. luciae* (St. Lucia) and *A. bonaiensis* (Bonaire) all have twelve macrochromosomes (Fig. 1). This is in agreement with the published karyotype of *A. carolinensis*², the only member of the genus previously examined.

A second group, *Anolis grahami* and *A. lineatopus* (from Jamaica), *A. lineatus* (Curacao), and *A. chrysolepis* (Trinidad), have fourteen macrochromosomes (Fig. 2).

Finally, *A. bimaculatus* (St. Kitts) has still another kind of karyotype in which eighteen to twenty chromosomes appear larger than dots. However, there is no sharp distinction between macro- and micro-chromosomes but instead a graded series from large to small (Fig. 3).

Table 1		
Major group	Species	Macrochromosomes
Alpha	Carolinensis series	
	<i>carolinensis</i>	12
Alpha	Latifrons series	
	<i>luciae</i>	12
Alpha	Bimaculatus series	
	<i>bimaculatus</i>	18-20 (see text)
Beta	Grahami series	
	<i>grahami</i>	14
Beta	Chrysolepis series	
	<i>lineatus</i>	14
	<i>chrysolepis</i>	14

Macrochromosomal number in 9 species of *Anolis*. Alpha and beta are the major groups of *Anolis*, and the various series are series of species within the groups, all as defined by osteological characters⁴.

Table 1 shows that in the four cases in which pairs of species belonging to the same series as defined by Etheridge⁶ were examined, there is no variation in macrochromosomal number. The major groups of Etheridge can be distinguished only by the fact that betas have 14

Fig. 1. Chromosomes of *Anolis carolinensis*, showing twelve macrochromosomes

Fig. 2. Chromosomes of *Anolis lineatus*, showing fourteen macrochromosomes

Fig. 3. Chromosomes of *Anolis bimaculatus*, showing a series of chromosomes grading from large to small with no sharp distinction between macro- and micro-chromosomes

macrochromosomes and alphas do not. Obviously further generalizations must await the examination of additional species within the genus.

These preliminary results suggest that karyotype will be a valuable taxonomic character for the elucidation of relationships and evolution of species groups within the genus *Anolis* as well as in other groups of the Reptilia. The karyotype can be obtained by the relatively simple techniques of blood culture.

I thank Dr. E. E. Williams, Dr. N. Feder and Dr. E. MacLeod of Harvard University for their advice and assistance; and Dr. P. Gerald and Miss S. Warner of the Boston Children's Hospital for introducing me to the techniques of blood culture and for use of their facilities. The photomicrographs were prepared by Dr. Feder. The

rk was carried out while I held a pre-doctoral fellowship in the U.S. National Science Foundation.

GENETICS

Measurements of Bovine Chromosomes

WE recently had an opportunity to study the karyogram a cell from a bovine male. Since we are interested in sperm nuclear areas in connexion with estimates of DNA individual sperm nuclei, it was of interest to measure projected areas of the chromosome images. The comments that follow all derive from the planimetric measurements (three times as complete sets by one observer, without reference to previously recorded measurements) from one karyogram.

The mean total area of the 60 chromosomes (corrected for magnification) was $281.25\mu^2$, making the mean area per chromosome $4.69\mu^2$. The smallest chromosome area is 0.203 times that of the largest, 0.400 times that of the mean. The largest area was 1.970 times that of the mean. Bovine chromosomes, except for the presumed sex chromosomes, are so morphologically similar that they cannot always be paired with certainty, so the cumulative distribution of chromosome sizes was plotted on probability semi-log graph) paper in ascending order of their calculated areas. Except for the seven largest chromosomes, the plot on log-probability paper approximates to a straight line. This is indicative of a skewed distribution sizes of bovine chromosomes.

The area of the presumed X chromosome was $7.85\mu^2$; the presumed Y it was $3.47\mu^2$. From these figures, and the total given above, one may compute the expected area of haploid (gametic) sets. A set containing the presumed X would have an area of $143.31\mu^2$ compared with $138.93\mu^2$ for a set containing the presumed Y. Thus there is an expected difference of 3.1 per cent in the area (and probably the mass) of haploid sets of chromosomes bearing either the X or Y. Could this difference (in X- and Y-bearing bovine spermatozoa) be detected by measurement of Feulgen-stained chromatin in bovine sperm nuclei? We think not. Using a Barr and Stroud integrating microdensitometer, we obtained a mean standard deviation of 0.033 units for 145 samples of 20 sperm nuclei each. From this one may calculate the expected least significant differences (*L.S.D.*) for different sample sizes. For samples of 1,000 the *L.S.D.* 0.01 turns out to be 0.234 units. For a sample mean of 15 units this is a difference of 1.6 per cent; for a sample mean of 20 units, the difference is 1.2 per cent. Thus it might be possible to detect a difference of 3.1 per cent between two populations of cells provided they were separated. The pooling of two normally distributed populations of equal size, with only a small separation in their means, results in a single population that approximates normality, but may be leptokurtic. To our knowledge there is no means of separating or identifying the X and Y gametes in bovine sperm populations, despite the attempts of Lindahl¹ by differential centrifugation and Gordon² by electrophoresis. The results of Nevo *et al.*³ would argue against the acceptance of electrophoresis as a general solution to the problem.

One other aspect was considered. Is it within the realm of possibility to see chromosomes in the sperm cell? We think not, despite the claims of Shettles⁴ for human

material. The measured area in plane of focus of Feulgen-stained bovine sperm nuclei varies from 20 to $35\mu^2$ (depending on individual variation, treatment of the semen sample, and method of fixation), which is about one-seventh to one-fourth of the area here estimated for haploid sets. Assuming equivalence of mass in the chromosomes of leucocyte cultures and the chromosomes of sperm nuclei, the chromosomes in the sperm nuclei must be layered 4-7 deep, making it unlikely that any optical system could resolve the individual chromosomes. Of course, the calculation above is an over-simplification which does not take into account the range of variability to be expected in the total areas of chromosomes from leucocyte cultures, but we have no reason to believe that the karyogram used was in any way unusual. The work reported was supported in part by a grant, GM-08753-03, from the U.S. Public Health Service, National Institutes of Health.

SOIL SCIENCE

Fixation of Metabolic Products in the Soil during Decomposition of Carbohydrates

SOME of the protein or amino-acids synthesized in the soil exist for a long time because they become resistant towards decomposition. About 40 per cent of the total amount of nitrogen in soils are thus found in amino-acids¹. This communication describes experiments dealing with the transformation of carbohydrate carbon into amino-acids and other compounds in soils.

Carbon-14-labelled cellulose and glucose were prepared from material originating from barley plants grown to maturity in a growth chamber in an atmosphere enriched with $^{14}\text{CO}_2$ (ref. 2). The specific activity of the preparations was about 80 $\mu\text{C/g}$ carbon; the nitrogen content was nil or insignificant. Cellulose (ground to pass a 40 mesh screen) and glucose respectively were added to soil portions in amounts corresponding to 500 mg carbon/100 g of dry soil, besides 10 mg nitrogen in NH_4NO_3 and water to 40 per cent of the water-holding capacity. Samples of 50 g were placed in 100-ml. Erlenmeyer flasks which were stored at 20° C in the dark connected to a respiration apparatus enabling absorption and measurement of the carbon dioxide evolved from the soil. Water evaporated was replenished every second week.

Soil samples were removed with intervals during the decomposition period and analysed as follows. Portions of 50 g without previous drying were shaken for 30 min with 200 ml. of 0.1 N $\text{Ba}(\text{OH})_2$ at room temperature. The filtrate of the suspension plus the washings of the residue was neutralized with sulphuric acid. The filtrate from the BaSO_4 precipitate was concentrated *in vacuo*, after which the carbon content and the radioactivity of the residue were determined². The soil extracted with $\text{Ba}(\text{OH})_2$ was boiled with 6 N HCl for 16 h under reflux, 10 g of air-dry soil plus 100 ml. of acid. The acid extract of the soil combined with the washings of the residue was repeatedly evaporated to dryness *in vacuo*. The part of the residue which was soluble in water was run through a H^+ saturated column of a cation exchange resin ('Amberlite IR-120'). The amino-acids retained by the column were desorbed by 2 N ammonia. After removal of the ammonia the concentration of α -amino-acid-N (ref. 3), carbon and radioactivity of the amino-acid solution were determined². Individual amino-acids were

detected on paper chromatograms. Carbon content and radioactivity of the untreated soil and the soil extracted with 6 N HCl were also determined.

Fig. 1 shows the results from an experiment in which cellulose was added to a medium loam soil (pH 6.1, carbon 1.4 per cent). It is seen that about 10 per cent of the original cellulose carbon was recovered in amino-acids after 12 and 30 days of incubation; after 90 days of incubation this value had decreased to 7 per cent, and after 300 days to 5 per cent. The amount of original cellulose-carbon incorporated in amino-acids constituted a considerable part of the total amount of original cellulose carbon remaining in the soil, about 40 per cent after 90 days of incubation and 30 per cent after 300 days. Maximum amount of original cellulose carbon in $\text{Ba}(\text{OH})_2$ extractable material (2.5 per cent) was observed after 12 days of incubation.

Addition of glucose to the soil mentioned above resulted in a larger incorporation of original glucose carbon in $\text{Ba}(\text{OH})_2$ extractable compounds, and in amino-acids during the first 5 days of incubation than observed for cellulose, but after 30 days of incubation the amounts incorporated were of the same size as mentioned for cellulose.

The $\text{Ba}(\text{OH})_2$ extracted material included a number of free amino-acids and polysaccharides which on hydrolysis yielded glucose and smaller amounts of other sugars. The amino-acids liberated during the treatment with 6 N HCl included 13 normal protein amino-acids besides glucosamine and galactosamine.

The clay content of the soil might be of importance for the fixation of metabolic products⁴. This relation was investigated in a few experiments. A sandy soil (pH 5.8, carbon 2.2 per cent) was mixed with washed quartz sand; to the sand was added a clay mineral, Wyoming montmorillonite, American Petroleum Institute Clay Mineral Standard No. 25, obtained from Ward's Natural Science Establishment, Rochester 3, New York. The clay was added in such amounts that the soil-sand mixtures con-

Fig. 1 Transformation of carbon added in cellulose into other compounds during decomposition in soil. The shaded areas of the columns indicate the amounts in per cent of the cellulose carbon added, the total areas of the columns indicate the amounts in per cent of original cellulose carbon remaining in the soil. 'Days' means days of incubation at 20° C. Columns marked 1 indicate original cellulose carbon in material extracted with 0.1 N $\text{Ba}(\text{OH})_2$, columns marked 2 indicate original cellulose carbon in amino-acids dissolved during treatment with 6 N HCl, columns marked 3 indicate original cellulose carbon remaining in the soil treated with 6 N HCl.

Fig. 2 Influence of added montmorillonite on the decomposition of glucose and cellulose in a soil-sand mixture. CO_2 means mg of carbon dioxide evolved per 100 g of dry soil-sand, 'days' means days of incubation at 20° C. The curves are summation curves and the numbers indicate per cent of montmorillonite added to the soil-sand from which the carbon dioxide production originates. The inserted histograms show the results of the chemical analyses of the soil-sand performed after 60 (glucose) and 90 (cellulose) days of incubation. The areas of the columns indicate the amounts of original glucose or cellulose carbon recovered in material extracted with 0.1 N $\text{Ba}(\text{OH})_2$ (dotted columns), and in amino acids dissolved during treatment with 6 N HCl (shaded columns). The values are stated in per cent of glucose or cellulose carbon added.

tained 0, 3, 5 and 10 per cent respectively of the clay besides 50 per cent of the soil, and sand to 100 per cent. Cellulose and glucose were added and the experiment performed and analysed as described above. Before addition the clay was prepared as follows. A 5 per cent suspension of the raw mineral was centrifuged for 10 min at 2,500 r.p.m. The suspension of particles not sedimented was run through columns of Na^+ and H^+ saturation exchange resin. The effluent suspension which had a pH of 2.2 was titrated to pH 5.8 (the pH of the soil with 0.5 N NaOH and centrifuged at 20,000 r.p.m. until all material had come down. The sediment was dried at room temperature *in vacuo* and ground thoroughly.

Fig. 2 shows that the presence of montmorillonite reduced the rate of the production of carbon dioxide from the soil-sand during the later stage of the decomposition, whereas it seemed to be of no importance during the first stage of decomposition during which about 40 per cent of the added carbon was evolved as carbon dioxide. The rate of carbon dioxide calculated to originate from soil humus was not, or only very slightly, influenced by the addition of the clay mineral.

The chemical analyses of the soil-sand mixtures after the decomposition period (Fig. 2, insets) showed that a larger percentage of the added carbon was recovered in amino-acids where the montmorillonite was added than in the controls without added montmorillonite. This seems to indicate that the reduced rate of production of carbon dioxide was a result of a protection of metabolic products towards microbial decomposition by adsorption to the montmorillonite⁵.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 4

BRITISH BIOPHYSICAL SOCIETY, PHYSICAL BIOCHEMISTRY GROUP (at the School of Pharmacy, Brunswick Square, London, W.C.1), from 11 a.m. to 6 p.m.—Meeting on "Light Scattering"

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion Meeting on "The Teaching of Mechanics of Machines".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (in the Shell Centre, Shell Centre, London, S.E.1), at 6.30 p.m.—Scientific Film Evening.

Monday, October 4—Wednesday, October 6

IRON AND STEEL INSTITUTE and the INSTITUTE OF METALS (at the Royal Commonwealth Society, Northumberland Avenue, London, W.C.2)—Joint Conference on "Machinability".

Tuesday, October 5

INSTITUTION OF MECHANICAL ENGINEERS, APPLIED MECHANICS GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion Meeting on "Acoustic Excitation and Mechanical Resonance".

Wednesday, October 6

COLOUR GROUP (Great Britain) (in the Physics Department, Imperial College, London, S.W.7), at 3.15 p.m.—Twenty-ninth Science Meeting part on the International Colour Conference in Lucerne (June 1965) and on the C.I.E. Committee Meeting in Basle. Speakers: Dr. B. H. Crawford, D. A. Palmer, Dr. R. W. G. Nunt and Mr. F. J. B. Wall.

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Mr. N. Capener: "An English seventeenth Century Emergency Hospital"; Mr. J. Shepherd: "The Civil Hospitals in the Crimea, 1855–1856"; Mr. D. L. Griffiths: "Medicine and Surgery in the American Civil War".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1) at 3.0 p.m.—Mr. R. Hollinghurst: "Radiation-Resistant Fluids and Lubricants".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at 100 Fenchurch Lane, London, E.C.3), at 5.30 p.m.—Discussion on "Filling Gaps in H.F./U.H.F. Service Areas" opened by Mr. L. F. Tagholm.

ROYAL MICROSCOPICAL SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—"Photomicrography—a Brain's Trust".

ENVIRONMENTAL GROUP (in the Department of Electrical Engineering, Imperial College of Science and Technology, Exhibition Road, London, W.7), at 5.45 p.m.—Extraordinary General Meeting. 6.30 p.m.—Discussion Meeting on "Existing Methods of Appraisal".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, RADAR GROUP (at Bedford Square, London, W.C.1), at 6 p.m.—Mr. H. W. Cole: "SECAR"—Modern SSR Ground Interrogator and Decoding Equipment".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, London, W.C.1), at 6 p.m.—Mr. L. G. Goodwin: "Comparative Pharmacology".

SOCIETY OF ENVIRONMENTAL ENGINEERS, PACKAGING GROUP (in the Mechanical Engineering Department, Imperial College, Exhibition Road, London, S.W.7), at 6 p.m.—Dr. J. Pendered: "Shock Response Analysis under Shock Spectrum".

SOCIETY FOR ANALYTICAL CHEMISTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 7 p.m.—Prof. T. S. West: "Some Special, Sensitive and Selective Reactions in Inorganic Trace Analysis".

TELEVISION SOCIETY (at the I.T.A. Conference Suite, 70 Brompton Road, London, S.W.8), at 7 p.m.—Discussion Meeting on "The Technical Future of British Television".

Thursday, October 7

ROYAL SOCIETY OF MEDICINE, UNITED SERVICES SECTION (at 1 Wimpole Street, London, W.1), at 5 p.m.—Surgeon Commander J. D. Walters and Dr. J. J. Brand: "Motion Sickness".

SOCIETY OF COSMETIC CHEMISTS OF GREAT BRITAIN (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7.30 p.m.—Dr. F. W. Scott Blair: "The Subjective Assessment of the Consistency of Materials in Relation to Physical Measurements".

Friday, October 8

BIOCHEMICAL SOCIETY (at the Middlesex Hospital Medical School, London, W.1)—453rd Meeting. Programme includes a Colloquium on "The Effects of Hormones on Nucleic Acid Synthesis".

Saturday, October 9

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Dr. J. Eric S. Thompson: "The Ancient Maya Civilization of Central America".

Monday, October 11

INSTITUTION OF MECHANICAL ENGINEERS, EDUCATION AND TRAINING GROUP (Joint Conference with the Schools Council, at 1 Birdcage Walk, Westminster, London, S.W.1), at 2.30 p.m.—Conference on "Applied Science and Engineering Activities in Schools".

UNIVERSITY OF LONDON (in the Botany Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. Drews (University of Freiburg): "The Cell of the Photosynthetic Bacteria in Light- and Dark-Metabolism" (further lecture on October 13).

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"Germany: a Regional Geography" (colour film).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PRINCIPAL BIOCHEMIST (with a good honours degree in chemistry or biochemistry and/or a Ph.D. or other higher qualification) in the Department of Chemical Pathology, Ashton Street, Pembroke Place, Liverpool, 3—The Secretary, The United Liverpool Hospitals, 80 Rodney Street, Liverpool, 1 (October 12).

PHYSICIST, BASIC GRADE, IN THE PHYSICS DEPARTMENT, to assist with the routine, development and research work of the department in the application of physics to medical problems (if necessary training will be given in all aspects of this work)—The House Governor, The London Hospital, Whitechapel, London, E.1 (October 14).

ASSISTANT LIBRARIAN (qualified librarian preferably with some experience in a college library)—The Clerk to the Governors, Woolwich Polytechnic, Wellington Street, Woolwich, London, S.E.18 (October 15).

PROGRAMMING ASSISTANT IN THE COMPUTING DEPARTMENT, to write programmes for the University EDF 9 computer and to assist in the general supervisory service of the Department—The Secretary of the University Court, The University of Glasgow, Glasgow (October 15).

RESEARCH ASSISTANT IN THE DEPARTMENT OF GEOGRAPHY to undertake the field work and photogrammetric plotting of aerial photographs necessary to compile a series of maps of an area in the Inner Hebrides—The Secretary of the University Court, The University of Glasgow, Glasgow, W.2 (October 15).

LECTURER (initiated, designed, constructed and used electronic devices, not necessarily medical) IN BIOLOGICAL ENGINEERING—The Secretary, The University, Aberdeen (October 16).

LECTURER (with special qualifications in social geography or social anthropology) IN GEOGRAPHY—The Registrar (Room 39, O.R.B.), The University, Reading (October 16).

SENIOR LECTURER IN MATHEMATICS; a LECTURER or ASSISTANT LECTURER IN MATHEMATICS, a LECTURER or ASSISTANT LECTURER IN STATISTICS; a LECTURER IN COMPUTATION, and a LECTURER or ASSISTANT LECTURER IN OPERATIONAL RESEARCH—The Registrar, Ref. 124Y/E, Bradford Institute of Technology, Bradford, 7, Yorkshire (October 18).

ASSISTANT STATISTICIAN (with an honours degree in statistics, or a first- or second-class honours degree (or equivalent qualification) in which statistics is a principal subject) in the Department's Headquarters in London—B. Johnston, Department of Education and Science, Curzon Street, London, W.1 (October 19).

LECTURER or ASSISTANT LECTURER (preferably with research experience, interest or qualifications in platyhelminth or nematode parasitology or the ecology and systematics of small animals) IN THE DEPARTMENT OF ZOOLOGY, Ahmadu Bello University, Northern Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 20).

RESEARCH ASSISTANT (with an honours degree in botany or an equivalent qualification, with an interest in taxonomy and preferably with some knowledge of bryophytes) IN THE DEPARTMENT OF BOTANY for participation in a project involving floristic and phytogeographical studies in antarctic bryophytes—The Assistant Registrar (Science), The University, Birmingham 15 (October 22).

LECTURER (with special qualifications in economic geography and quantitative methods) IN THE DEPARTMENT OF GEOGRAPHY, University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 25).

SENIOR LECTURERS and LECTURERS IN THE DEPARTMENT OF PHYSICS, University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 25).

LECTURER IN GEOLOGY AT FOURAH BAY COLLEGE, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 28).

READER IN COMPUTER SCIENCE AT THE INSTITUTE OF COMPUTER SCIENCE, to lead a small research group concerned with the general design and use of future computing systems including problems of man-machine communication—The Academic Registrar, University of London, Senate House, London, W.C.1 (October 29).

SCIENTIFIC INFORMATION OFFICER (with a botanical or agricultural degree, the ability to write correct English, and preferably a knowledge of foreign languages) AT THE COMMONWEALTH BUREAU OF PLANT BREEDING AND GENETICS, Cambridge, for work which includes abstracting, editing, classification of biological literature and dealing with scientific enquiries—The Director, Commonwealth Agricultural Bureaux, School of Agriculture, Cambridge (October 30).

JUNIOR LECTURER or LECTURER (with at least a B.Sc. (Hons.) degree, and preferably some experience in radioisotope work) IN SOIL SCIENCE, Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

LECTURER or SENIOR LECTURER (with a degree in agricultural science or science, and experience in soil fertility work, either in the field or the laboratory) IN SOIL SCIENCE at Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

SENIOR LECTURER, LECTUREL or JUNIOR LECTURER (one or two appointments) (preferably with research experience or special interests in (a) plant physiology, particularly of the cell and tissue levels, (b) morphology and physiology of lower plants; or (c) cytology and histochemistry) IN THE DEPARTMENT OF BOTANY, Massey University of Manawatu, Palmerston North, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

CHAIR OF HAEMATOLOGY at St. Bartholomew's Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (November 1).

CHAIR OF PLANT PHYSIOLOGY within the Waite Agricultural Research Institute, University of Adelaide, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, November 1).

LECTURER (graduate in microbiology or biochemistry) IN BACTERIOLOGY—The Secretary, Trinity College, Dublin, 2, Republic of Ireland (November 1).

LECTURER (with a higher degree in anthropology/sociology, experience in conducting independent research, and preferably some teaching experience) IN ANTHROPOLOGY at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 13).

SENIOR LECTURER (competent circuit engineer with modern experience and a knowledge of digital computers, and preferably analytical ability and lecturing experience) IN ELECTRICAL ENGINEERING at the University of

Adelaide, South Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W. 1 (Australia, November 15).

ASSISTANT LECTURERS or LECTURERS (3) IN THE DEPARTMENT OF PHYSICS—The Registrar, The University, Liverpool, quoting Ref. CV/290 (November 27).

LECTURERS (with a good honours degree and a keen research interest in any branch of electronics and control engineering) IN THE SCHOOL OF ENGINEERING SCIENCE, ELECTRONICS AND CONTROL DIVISION—The Registrar, University College of North Wales, Bangor, North Wales (November 30).

ASSISTANT LECTURER, GRADE B, to teach human anatomy, physiology and hygiene and possibly some general science, together with biology to G.C.E. Advanced Level—The Registrar, Derby and District College of Technology, Kedleston Road, Derby.

ASSISTANT LECTURER (honours graduate with suitable postgraduate experience) IN PHYSICS—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W.3.

ASSISTANT LECTURER (with appropriate qualifications in biology, mycology or botany, and preferably special qualifications in plant mycology or general mycology) IN BIOLOGY IN THE DEPARTMENT OF APPLIED MICROBIOLOGY AND BIOLOGY—The Registrar, University of Strathclyde, Glasgow, C.1.

CHIEF TECHNICIAN (with appropriate technical qualifications and wide practical experience) IN THE SCHOOL OF BIOLOGICAL SCIENCES AT BATH, to be responsible for the overall control of technical services and the ordering of materials and equipment in the School—The Secretary and Registrar, Bristol College of Science and Technology, Ashley Down, Bristol, 7, quoting Ref. CST. 65/90.

ELECTRONICS TECHNICIAN (preferably with a National Certificate in Electrical Engineering or equivalent) IN THE BIOLOGICAL LABORATORY, to be responsible for the maintenance and construction of electronic instruments used in research and teaching—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

FIELD ASSISTANT (Female) (with a degree in zoology, preferably with an interest in geography or geology) at Preston Montford Field Centre, near Shrewsbury—The Secretary, Field Studies Council, 9 Devereux Court, Strand, London, W.C.2.

GRADUATE RESEARCH OFFICER (preferably with experience in medical statistics, biometry or genetics) IN STATISTICS in the Oxford Record Linkage Study and Unit of Clinical Epidemiology—The Medical Director, Oxford Record Linkage Study, Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford.

LECTURER (honours graduate in zoology with subsidiary qualifications or interest in physiology) IN ZOOLOGY IN THE BIOLOGY AND ZOOLOGY DEPARTMENT—The Principal, Norwood Technical College, Knight's Hill, London, S.E.27.

LECTURER or ASSISTANT LECTURER (preferably with a special interest in social statistics, social administration or industrial sociology) IN SOCIOLOGY, to assist with teaching for London honours degrees in Sociology—The Registrar, Portsmouth College of Technology, Hampshire Terrace, Portsmouth, Hampshire.

LIBRARIAN (qualified person or graduate)—The Administrator, Department of Biochemistry, University of Oxford, South Parks Road, Oxford.

MASTER (preferably graduate in mechanical sciences or engineering) TO TEACH MATHEMATICS AND SOME PHYSICS—The Headmaster, Oundle School, Peterborough.

MASTER TO TEACH MATHEMATICS to scholarship level—The Headmaster, Monkton Combe School, near Bath, Somerset.

ORNITHOLOGIST (university graduate in zoology) with the Canadian Wildlife Service, Quebec City, to undertake ecological studies of migratory bird populations with particular emphasis on the distribution, numbers, locations and migrant patterns of waterfowl and the evaluation of their habitat—Technical and Scientific Requirements Group, Civil Service Commission of Canada, Ottawa 4, Ontario, Canada, quoting Ref. 65-1350K.

PHYSICIST (well qualified and experienced, able to teach to university scholarship level)—The High Master, Manchester Grammar School, Manchester, 13.

PHYSICIST (with an honours degree) IN THE PHYSICS DEPARTMENT for work involving the clinical and biological uses of ionizing radiation—The Physics Department, Westminster Medical School, Horseferry Road, London, S.W.1.

PROFESSOR IN PHYSICAL CHEMISTRY—Prof. Harry E. Gunning, Head, Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada.

RESEARCH ASSISTANT (civil or chemical engineering graduate) IN THE DEPARTMENT OF CIVIL ENGINEERING, to investigate fluidization-flocculation processes in water purification—The Secretary, University College, Gower Street, London, W.C.1.

RESEARCH ASSISTANT IN THE DEPARTMENT OF PHYSICS for research on plasma generation by high power lasers—The Registrar, University of Essex, Wivenhoe Park, Colchester, Essex.

RESEARCH ASSISTANT (with a good honours degree in sociology) IN SOCIOLOGY—The Registrar, Portsmouth College of Technology, Hampshire Terrace, Portsmouth, Hampshire.

SOIL CHEMIST (national of the United Kingdom or the Republic of Ireland, with either an honours degree in agricultural chemistry (soils and plants), or a degree in chemistry with postgraduate experience in agricultural analysis (soils and plants), and preferably experience in soil and plant analysis) with the East African Common Services Organization, to carry out and supervise soil and plant analysis and to help develop and investigate new methods—The Appointments Officer, Ministry of Overseas Development, Room 301, Eland House, Stag Place, London, S.W.1, quoting Ref. RC 213/214/04.

TECHNICIAN or SENIOR TECHNICIAN (with a good knowledge of general laboratory practice, and preferably special experience in experimental and microscopical cell studies or electron microscopy) in the Analytical Cytology Section, to assist in work on cell ultrastructure and function—A. D. Greenwood, Department of Botany, Imperial College, London, S.W.7.

TECHNICIAN (preferably with experience in the food or pharmaceutical industries) TO TAKE CHARGE OF BIOCHEMICAL ENGINEERING PILOT PLANT—The Establishment Officer, University College, Gower Street, London, W.C.1, quoting Ref. Chem. Eng./3.

NEW grating SP200G infrared spectrophotometer

high resolution

Unicam now offers all the advantages of a grating filter monochromator combined with the proved features of the SP200 prism spectrophotometer. The first order of the NPL grating is isolated by four interference filters, brought into play by an automatic mechanism exclusive to Unicam. The resolution is as high as 3 cm^{-1} at 3000 cm^{-1} and stray light is less than 1% throughout most of the range and never exceeds 2%. The wavenumber accuracy is better than 2 cm^{-1} at 1000 cm^{-1} and 4 cm^{-1} at 3000 cm^{-1} . To this performance are added the advantages of the flat bed recorder, the accessible sample compartment and the convenient operation of the SP200. The new SP200G is constructed and finished to the high degree of precision for which Unicam instruments are famous. Descriptive literature is available on request.

AGAROSE

A neutral galactose polymer obtained from Agar by a unique method using reagents having no toxicity.

- * Negligible electroendosmotic properties.
- * High gel strength.
- * Non-toxic.
- * Minimum adsorption properties.

This product and many ENZYMES and RELATED BIOCHEMICALS of the highest possible integrity are produced entirely in our own laboratories.

SYNCHRONOUS CHRONOSCOPE

for scientific and industrial use supplied to industrial organizations and research establishments. Available for panel mounting. Enquiries are welcomed.

Camerer Cuss supply all types of timing units, and sectional catalogues and leaflets are available for all types of timers. Special equipment can also be manufactured to suit specific requirements.

A superbly accurate instrument, this fully portable chronoscope is suitable for AC mains operation 110/220v. It measures:

- Duration of an Impulse
- Interval between two impulses
- Duration of an Interruption
- Duration between two interruptions

PRECISION INSTRUMENTS

Immersion Refractometer

The Immersion or 'dipping' refractometer, as it is sometimes known, is a versatile instrument yielding a high accuracy—0.00004 on the majority of liquids in common use in science and industry. The principal function is of a comparative nature, measuring small differences in index between similar samples. The normal range of 1.325 to 1.597 is made up using 7 interchangeable prisms, each covering a span of approximately 0.04. The first range prism (1.325 to 1.367) is also available in a water jacketed prism box as illustrated. A recent addition is a flow cell holding about 4 ml. of sample, intended for repetitive measurements where the fresh sample flushes out and replaces the previous sample. The unit is fully water jacketed for close temperature control and may also be used for continuous flow measurements.

RESEARCH AND DEVELOPMENT IN BRITISH INDUSTRY

PROF. J. W. MITCHELL'S stimulating Jubilee Memorial Lecture to the Society of Chemical Industry (*Nature*, 207, 113; 1965) on the organization of basic research for the British chemical industry was followed in May by Sir Ronald Holroyd's Brotherton Memorial Lecture to the same Society at Leeds, in which he discussed some aspects of research and development in that industry. More recently, at the annual general meeting of this Society in Cardiff in July, Mr. K. Piercy considered the broader picture of the chemical industry in a changing world, touching on such topics as the problems presented by technological change, research policy, logistics, long-range planning and the demands made on management and staff. Similar ground was covered by Dr. J. Taylor in a lively and provocative address entitled "Restrictive Practices", when he was awarded the Society's Medal at that meeting. Taken with Mr. J. C. Duckworth's eleventh Graham Clark Lecture to the Institution of Mechanical Engineers, "Incentives to Innovation and Invention", these lectures provide a highly stimulating and suggestive commentary on British industry in general and on the chemical industry in particular, which is worth examining in the context of the organization and activities of the Ministry of Technology and of Britain's economic situation generally.

Early in his address, Sir Ronald Holroyd, for example, points out that research in industry aimed primarily at commercial objectives has contributed greatly to the general body of scientific knowledge, and that such fields as colloid science, crystal-habit control and the chemistry of photography have developed very largely through industrial contributions. Such research work inside industry has called for the same degree of ingenuity and skill as any other form of research, and has involved more fundamental work than is commonly imagined. Indeed, the possibilities of conducting fundamental research in industry are considerably greater than is often appreciated, especially perhaps by teachers and others who may influence the choice of a career by a young graduate.

Sir Ronald is not, however, concerned with this point more than to emphasize the advantage which the greater resources of the industrial firm may confer in an integrated attack and the dependence of the future growth, diversification and productivity of chemical industry on the volume and efficiency of its own internal research effort. He is not unmindful, however, of the benefit derived from academic research or that in some fields Government institutions could provide valuable, if strictly limited, assistance. He is concerned, though, more especially with the way in which new discoveries and inventions in industry emerge: here his address runs parallel with that of Mr. Duckworth's.

Sir Ronald points out that the really successful company is one which, in addition to seeking new applications for existing knowledge, has the imagination to pick out potentially profitable objectives not obtainable with existing knowledge and the ability to work out an approach to these objectives through its own facilities for research and development. Success in identifying such objectives depends very largely on the early recognition of existing or future needs, whether in the company itself, in the industries it serves or in the community at large, and

Sir Ronald adds that this responsibility must be spread over all branches of the company. The ordinary research scientist is not the most likely person to recognize or to assess the importance of such needs: his skill and inspiration are the dominant factors in seeking a scientific breakthrough towards a selected objective.

Accordingly, Sir Ronald reminds us that research, including technical development, cannot be treated in an industrial setting as an isolated function, but must be closely integrated with the other activities of the firm. Scientists in industry must recognize that they are a part of the overall management team and look to the practical and economic achievements of the company for their main personal satisfaction in their work. This he regards as the essential difference between research within and without industry, and it obviously has a close bearing on the ability of an industry to attract competent scientists. However, in his lecture, Sir Ronald stresses the responsibility it places on management for making effective use of its scientists, including the deliberate diversification of their expert experience. Neglect of this could be a potent factor in the shortcomings of the chemical industry which have led it to lose ground to foreign competitors to an extent for which the Economic Development Council could find no obvious explanation.

The Council did indeed suggest that uncertainty about the future growth of the economy was leading to hesitant investment, and that the high cost of British coal and electricity, as well as the comparatively low British tariff on the newer plastics, might be hidden obstacles. None of these, however, bears closely on the point discussed by Sir Ronald and by Mr. Duckworth, and it is worth noting that Mr. Duckworth, so far as the individual is concerned, discounts the primary importance of material incentives. Both here and in his comment that significant technological advances now tend to be made by teams rather than by individuals, his views support Sir Ronald's, at least by implication. He challenges the academic attitude towards patenting, as perhaps might be expected from the chairman of the National Research Development Corporation, and stoutly champions the policy of energetic filing and exploitation of patents.

Mr. Duckworth's views on industrial and national incentives are likewise largely derived from his experience with that Corporation. However, he points out that inventions and innovation are not necessarily meritorious in themselves but only so far as they contribute to higher efficiency and enable us to compete more effectively in world markets. While all significant technological information available in the United States is also available in Britain, the output per worker in the United States is in general 2.5-3 times that in British industry. Britain's immediate problems, he believes, are concerned mostly with management and with the attitude of workers to their jobs. He suggests that a thorough study of the reasons underlying this difference would be a most potentially rewarding research programme.

Mr. Duckworth again agrees with Sir Ronald when he remarks that, in the long run, achievement of a steady increase in productivity can be achieved only by the introduction of new processes and products. It is in this context that he suggests that a main purpose of taxation

should be to ensure, so far as possible, that individual firms, while looking after their own interests, act in the national interest also. Nevertheless, a recent survey has shown that when deciding whether or not to install a new process only 16 per cent of firms make prior allowance for all available tax incentives in their calculations. This may be an indictment of management but, as Mr. Duckworth observes, it makes it difficult to see what the next stage should be.

Mr. Duckworth sees four areas where direct Government action is, or would be, advisable in the national interest. First are those few projects of great significance and public interest where the research and development expenditure or capital cost involved are too great to be shouldered by an individual firm or groups of firms—as in the development of civil aircraft or nuclear power. It might be added that we have yet to elaborate really satisfactory procedures to provide the basis for even Government decisions in such major technological developments. Mr. Duckworth suggests that scientifically trained executives would make a great contribution in Government by ensuring that scientific method was applied in Government procedures so that the maximum possible information was available before decisions were taken.

Secondly, there is the analogous situation of a medium-sized project for which, as with the hovercraft, there is no particular industry in existence with the potential or expertise to develop it fully. The third area which he instances is concerned with the fact that a relatively long-term view is required as compared with the relatively short-term view which directors are usually compelled to take in the interests of their shareholders. The fourth is that where the estimated benefit to the innovating industry may provide insufficient incentive to proceed, although the benefit to the national economy as a whole may be considerable. Here a start has already been made with the use of cost/benefit analysis, and Mr. Duckworth concludes his lecture by stressing the vital part which the engineer or scientist who turns to management could play. It is to the application of scientific method and results to management and to new products and processes that we must look for increased productivity, though the creation of a society which welcomes innovation also depends largely on a re-orientation of our sense of values.

Much of what Mr. Duckworth says in this lecture is reflected in the closing part of Sir Ronald Holroyd's lecture, particularly in reference to management and the methods of assessments available or in use. Both are also conscious of the critical importance of recruitment, of ensuring that a due proportion of talent is attracted to engineering and technology and that the idea that industrial scientific activities are intellectually second-rate should be firmly dispelled. Mr. Piercy does not refer to this recruitment problem, but in referring to management and staff he stresses the exacting demands made on them in the chemical industry, with the result that their jobs are correspondingly more intellectually satisfying and interesting than in the past. He believes that the industry could do more to ensure that its able young men receive first-rate training in management at appropriate stages in their career and that, after giving them the opportunity to broaden their experience, the best use is made of their abilities.

Mr. Piercy's confidence in the ability and professional competence of such management in chemical industry is the more significant in that his address treats more

specifically the policy and export performance of the industry which the Economic Development Council for the industry has since criticized. In referring to long range planning, he does not mention the uncertainty stressed by the Council, but he admits that its export performance does not compare well with similar bodies in other countries. He is also concerned at the rise in chemical imports, for which he suggests no specific reason. Commenting on the trend towards larger plants he believes that the risk of excess capacity has been over exaggerated; while this trend makes the choice of a site more difficult, he agrees with Sir Paul Chambers as to the importance of really large markets.

On all this Dr. Taylor's lively address makes a most stimulating gloss. He puts the question of restrictive practices very fairly and pertinently in its proper context and in a way that indicates where the particular responsibility lies. Restrictive practices are, he points out among the restrictions and inhibitions on our adaptability and rate of progress imposed by the illogical forces derived from man's past which dominate our behaviour. To recognize this is a first step toward eliminating the restrictive practices which, Dr. Taylor agrees, must be cut out if we really mean to improve our material prosperity. They are, in fact, widely present throughout our society and in so far as they do, as some argue, arise out of social and economic cleavages. Dr. Taylor considers that our troubles are due in greater part to a lack of leadership.

Dr. Taylor makes one point that is often overlooked in discussing our economic situation to-day: as a people, we made two all-out efforts in war in little more than thirty years, and whereas the defeated nations had help from outside in their subsequent struggle to survive, the British people have never had the opportunity to relax. It is equally important to note that Dr. Taylor does not commit himself that a materialistic objective is necessarily wise and this should be remembered when he emphasizes that British industry is more highly manned than its American counterpart and that only if the profit per person in productive industry is high can the standard of living in Britain be improved and capital resources built up. That the chemical industry is so highly manned should induce a careful study with the view of reducing manpower. To cut out restrictive practices is one way of achieving this, provided our diagnosis of those practices is accurate and complete, and takes account of those which arise from outside—more particularly from Government regulation or interference and tax systems.

Dr. Taylor faces the difficulties of this problem fairly, putting his finger on some of the real sources of friction, such as the differentiation between the salaried staff and the pay-roll, particularly in respect of redundancy. Without defending obsolete ideas and practices in the Trade Unions, he points out that their critics also sometimes fail to take account of changed conditions and that on the staff side too restrictive practices are to be found quite inconsistent with responsibilities which are the counterpart of their privileges. Moreover, if it is difficult enough for people of advanced education to adapt themselves to change and even the *tempo* of change, it is much more difficult for those who left school at the age of fourteen to make the transition from a well-established routine to fundamentally different methods of working. Adaptation and innovation in an industrial society present essentially an educational problem. A much clearer understanding of the problems of adaptation in an industrial society is needed and, as Dr. Taylor adds, a more

sitive approach to the educational problems involved overdue.

There is sense and insight in Dr. Taylor's comments on management, on the inherent weakness of controls and of organization, necessary as they are. If management must bear the major share of responsibility for stricture practices, the fundamental need is leadership at all levels, and, in this, individuality and personality must to an extent that educational authorities—and others—are liable to forget. Moreover, the type of leadership we need to-day will not concentrate on economic efficiency to the detriment of the rights and dignities of the individual. However, here Dr. Taylor recognizes that national policy also has a part to play, particularly if we are to take work to the workers rather than transfer workers to the work.

While this group of lectures and addresses is of interest in illustrating the outlook and approach of responsible leaders within the chemical industry as much as for their diagnosis of some defects on which the National Economic Development Council has commented, the importance attached to management is impressive and supports much that was said at the recent Cambridge meeting of the British Association for the Advancement of Science. The idea that the chemical industry generally is backward is scarcely enable in the light of these addresses, but their challenge to education and to Government is unmistakable. Neither in industry nor in Government is there room for complacency, and in the chemical industry as elsewhere the challenge of Britain's economic position will only be met by the response of efficient management and of workers and staff is matched by appropriate Government policy and structure for the assessments on which policy should be based.

NOBEL LECTURES AND SCIENTIFIC METHOD

Physics

Nobel Lectures including presentation speeches and laureates' Biographies 1922–1941. Pp. xii + 456. Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 160s.

THIS handsome volume is the second of three volumes which present the Nobel Prize Lectures in Physics in the English language accompanied by the presentation addresses and short biographical notes. The Nobel Foundation hopes that they will serve to supplement its annual publication *Les Prix Nobel*. The publishers state that the translations of Lectures which were not given in English were prepared by the Babylon Translation Service of London: it is to be regretted that the English is often irritatingly bad, for example, "Allow me to refresh your memories what is the Laue phenomenon" (p. 254). It is curious, also, to have the short sentence which justifies the bestowal of the Prize listed, in each case, as "Motivation" in the contents. The Lectures are preceded by presentation addresses which are a valuable aid to the reader, although these sometimes exceed in length the lectures by the laureates.

The period 1922–41 is a fascinating one, since it contains the development of revolutionary ideas associated with the names of Bohr, de Broglie, Heisenberg, Schrödinger and Dirac, as well as vital experiments concerned with the ultimate structure of matter made by laureates from Millikan (1923) to Fermi (1938) and Lawrence (1939). The Lectures are therefore particularly interesting from the point of view of scientific method and the philosophy of science, since they exemplify the modern method of

starting with mathematical equations and then attempting to interpret their solutions later. This, of course, does not supply causal explanations but permits predictions which, it is nowadays claimed, are all that can be hoped for.

Prince Louis Victor de Broglie (laureate 1929) was the pioneer of the hypothesis of matter-waves. He says, "experiment which is the final judge of theories has shown that the phenomenon of electron diffraction by crystals actually exists and that it obeys exactly and quantitatively the laws of wave mechanics" (p. 255), and concludes "this wave is no myth". He nowhere actually states what the waves are waves of, and he accepts the prevailing word-magic which, by using the Latin word *quanta*, avoids saying what the quantities are quantities of. He appears to avoid actually calling these quantities 'energy'—rightly, because this is a purely metrical term which, therefore, could never be absorbed by any atom and cannot constitute a causal explanation. In recent years de Broglie has resumed the attempt he made in 1927 to give a causal interpretation to wave-mechanics; he has now, he says, "The growing impression that the majority of physicists who have yielded to these exaggerated abstract tendencies have too easily desisted from forming an intelligible representation of the phenomena of quanta physics"¹.

In 1932 the laureate was Werner Heisenberg—"for the creation of quantum mechanics . . .". He put forward the well-known thesis that we must forgo a visual description of the atom and maintained that the laws of Nature are basically statistical.

Erwin Schrödinger (1933) summed up his epistemological views somewhat obscurely as follows: "I would define the present state of our knowledge as follows. The ray or particle path corresponds to a *longitudinal* relationship of the propagation process (i.e., in the *direction* of propagation), the wave surface on the other hand to a *transversal* relationship i.e., *normal* to it). Both relationships are without doubt real: one is proved by photographed particle paths, the other by interference experiments. To combine both in a uniform system has proved impossible so far. Only in extreme cases does either the transversal, shell-shaped or the radial, longitudinal relationship predominate to such an extent that we *think* we can make do with the wave theory alone or with the particle theory alone".

Paul A. M. Dirac, who shared the 1933 Prize with Schrödinger, explains how he derived a relativistic wave-equation involving the invention of new mathematical variables, and states that these "give rise to the spin of the electron" (p. 322), but he also admits frankly that these variables also "give rise" to some rather unexpected phenomena. (Mathematical terms and operators cannot, of course, "give rise" to anything physical. They can only give rise to other mathematical expressions. This illustrates the confusing misuse of language in which this subject is involved.) One unexpected phenomenon is that "an electron . . . must actually have a very high-frequency oscillatory motion of small amplitude superimposed on the regular motion which appears to us". As a result, "the velocity of the electron at any time equals the velocity of light" (p. 322): he does not comment on the fact that this contradicts the theory of relativity from which the conclusion has been derived, "but one must believe in this consequence of the theory, since consequences of the theory which are inseparably bound up with this one, such as the law of scattering of light by an electron, are confirmed by experiment". Scientists have not always agreed with this attitude to a theory: it raises the difficult problem of the status of an equation some of the interpretations of which are verified, and some are not, or are meaningless, or even contradictory. With equal frankness, Dirac discusses another difficulty—that the equations which led to the prediction of the positron also predicted negative energy-states, which are, of course, physically meaningless; but once again "we must

find some meaning for these states". In this case he is driven to the *ad hoc* hypothesis that they are nearly all "occupied" by electrons and to the further *ad hoc* hypothesis that if they were fully occupied they would be completely unobservable. Unoccupied negative energy-states are first called "holes" ("for brevity") and then a hole is said to be "just like an ordinary particle", and finally, the hole is called a positron. But despite the *ad hoc* hypotheses and the word-magic, energy-states are not particles, whether occupied or not, and are not observed but calculated.

In 1937, the laureates were Clinton J. Davisson and G. P. Thomson. In Thomson we see the spirit of British empiricism and a cautious and critical approach: "I am predisposed by nature in favour of the most mechanical explanation possible . . . it might be best, and it is certainly safer, to keep strictly to the facts and regard the wave-equation as merely a way of predicting the results of experiments".

After several unsuccessful attempts to give some physical meaning to matter-waves, mathematical physicists have realized that Eddington was right in calling wave mechanics "a dodge—and a very good dodge too"². But dodges are not physical theories, and diffraction does not necessarily imply waves³. We still await a Nobel Lecture which will give us a physical theory of the atom.

ELECTROCHEMISTRY

The Encyclopedia of Electrochemistry

Edited by Clifford A. Hampel. Pp. xviii + 1206. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1964.) 35 dollars.

Proceedings of the First Australian Conference on Electrochemistry

Held in Sydney, 13th–15th February, and Hobart, 18th–20th February, 1963. Edited by J. A. Friend and F. Gutmann, assisted by J. W. Hayes. Pp. xvi + 954. (London and New York: Pergamon Press, 1965.) 200s. net.

MANY of us will have our own, we suspect, limited ideas as to the scope of electrochemistry, and an 'encyclopaedia' in this field might accordingly appear to be a publishers' 'gimmick' rather than a worth-while proposition to the potential user. An evening's perusal of the present volume, however, will convince even the most complacent reader that here is a book which not only fully justifies the title "*Encyclopedia*" but is also an authoritative up-to-date reference book of high scientific standard. The individual items, numbering 400–500 and written by nearly 300 special contributors, are substantial articles; they average about 2,000 words or more, are well supported by block diagrams, photographs and data tables and in addition in most cases conclude with relevant and important literature references. The items covered are theoretical and practical, laboratory and industrial, as indicated briefly by the following range quoted in the introduction: batteries, corrosion, insulation, electrodeposition, luminescence, electro-organic, electrothermics, industrial processes, theoretical electrochemistry and electrochemistry in biology and medicine. But such a classification does not convey anything of the wide range of substantial articles in each of these fields, nor prepare the reader for those no less important articles that cannot be so classified. Anyone whose work or interests impinge on matters in any way connected with electrochemistry in its widest sense is sure to find articles of direct interest in this book. The editor is by no means exaggerating when he states that this book will be especially useful to physical, inorganic and

analytical chemists, to chemical corrosion, electronic or electroplating engineers, to metallurgists concerned with non-ferrous metals and with basic studies of high temperature and surface phenomena, to physicists specializing in electronics and to workers in biophysics and neurology.

To proceed from the general to the particular and discuss specific articles may not be helpful because of the wide range of readers catered for. The university student, for example, will be attracted by such articles as those by Dr. Parsons on the double-layer and on electrode kinetics, by Dr. Eisenberg on concentration polarization and by Prof. Read on hydrogen embrittlement. Nor will he be confused by electrode sign conventions; the European and American conventions are both clearly discussed and unambiguous, used throughout with the American convention reserved for oxidation potentials. Thus those to whom the use of the American sign convention in text-books of electrochemistry is anathema may safely refer their student charges to this book. But to mention in this way items of particular interest to one class of reader is to single out just a few to the detriment of the hundreds of other items equally demanding recognition. One high-light which must be mentioned, however, is the inclusion of a most comprehensive "Table of Electrode Potentials and Temperature Coefficients".

This, then, is a book which, though it may have arrived unasked for and unexpectedly, nevertheless has arrived and is here to stay. The contributors are all acknowledged specialists in their fields and each has now confirmed and enhanced his own reputation. Not least in this respect the editor, C. A. Hampel, who may feel justly proud of his success in harnessing so much electrochemical knowledge in one substantial volume. Typographical errors are insignificant; one might, however, wonder what is meant by "incomprehensible" liquid (p. 159), and one could be misled by the use of "free enthalpy" (p. 429) when referring to Gibbs free energy.

THE justification for the First Australian Conference on Electrochemistry embracing virtually all the modern facets of electrochemistry, pure and applied, lies in two facts. The first is the present considerable interest in electrochemistry, reflected in a four-fold post-war increase in the percentage of physical chemistry research papers appearing in the field of electrochemistry; the second is the significant proportion of this work which is being carried out in Australia. The volume under review represents a substantial contribution to present-day electrochemical literature and offers unequivocal evidence of the success of this Conference. It is certainly a publication which should be read in part or in its entirety by all those interested in electrochemistry; our only reservation springs from the fact that *Proceedings* of conferences, even international ones such as this, often do not find their way into published abstracts. One wonders if the many original contributions would eventually reach wider public had they been published in the usual journal and the present *Proceedings* limited to extended abstracts. This, however, is a fault of the system, not of the Conference.

The *Proceedings* contain, with the exception of two papers, a full and detailed record of all the contributions amounting to some 60 papers. About one-half of these were contributed by visiting scientists mainly from the United States and Canada, although several were from European, Japanese, Indian and Egyptian workers. Contributions by Russian workers were unfortunately absent.

The Conference was held partly in Sydney and partly in Hobart. Each of the twelve sections of the Conference was introduced by a different chairman; this provided the key to the success of the Conference and contributed in no small measure to the justification for this book. The choice of chairmen, all distinguished in their field, was excellent and each in his address provided a lucid and detailed review

f the main theme and so prepared the way for the succeeding contributed papers. The range of topics covered is well illustrated by the following list of the twelve sections: solid-state chemistry, thermodynamics of electrolytes, corrosion, theory of double-layers, electro-analytical methods, applications (electroplating, anodizing), non-aqueous electrolytes, molten salts, fuel cells, electrode processes, electrochemical processes, electrowinning and electrorefining. The major sections are those concerned with fundamental research, and these give substance to Prof. J. O'M. Bockris's comments in the foreword that electrochemical research is now heavily concerned with electrode kinetics ('electrodics') and with kinetics and theories of electrode processes to the virtual exclusion of thermodynamic equilibrium studies. The sections on applied electrochemistry will prove no less interesting to those concerned with applications, but we consider that these sections might with advantage have been brought together, so permitting a greater continuity in the theoretical sections.

It is invidious perhaps to single out individual contributions. The review papers by chairmen Ross Macdonald (and C. A. Barlow) and by J. O'M. Bockris on the theory of the double-layer and electrode processes respectively are of particular interest because of the difficulties attending work in these fields. Perhaps not unexpectedly the number of contributions to these sections were not as numerous as in some of the other sections. In the section on electrode processes, a paper by Horuti, Matsuda, Enyo and Kita on the mechanism of the hydrogen evolution reaction is of considerable interest, as also is that by Christov on the application of quantum mechanics to electrode kinetics. In the section on electrochemical processes mention should be made of the chairman's address and a stimulating paper by Bockris, Devanathan and Müller on the structure of charged interfaces. But this is to mention a few among the many excellent papers the degree of importance of which will vary according to the particular interests of the reader.

The production of the book is excellent, and Pergamon Press have fully maintained the high standard set by F. Gutmann and M. Bloom, who organized the Conference and, with J. A. Friend, edited the *Proceedings*. The price at £10 is not excessive for such a book.

NUCLEAR AND RADIOCHEMISTRY

Nuclear and Radiochemistry

By Dr. Gerhart Friedlander, Joseph W. Kennedy and Dr. Julian Malcolm Miller. Second edition. Pp. xi + 585. (New York and London: John Wiley and Sons, Inc., 1964.) 68s.

"FRIEDLANDER, Kennedy and Miller" is still recognizably the same excellent text as "Friedlander and Kennedy", though the format is new, the order of the chapters has been changed, and there are substantial additions to the subject-matter, as well as some deletions. On balance, the new edition is longer by roughly one-third compared with its predecessor. Prof. J. M. Miller of Columbia University has replaced the late Prof. J. W. Kennedy as author, though Kennedy's name has deservedly been retained on the title-page. Not unnaturally, the book still has an American slant, but this in no way invalidates it for other countries.

In their preface the authors state that "the book is still intended as a text for an advanced undergraduate or first-year graduate course; but a significant aspect of its modernization is found in the greater depth of treatment accorded to many topics, particularly theoretical ones". The new material includes greatly expanded treatments of nuclear reactions and radioactive decay processes, accounts of new types of accelerators, counters and other instru-

ments, and two completely new chapters, the first on models of the nucleus, and the second on the Mössbauer effect and other nuclear processes that can be made to yield chemical information.

It is characteristic of the book that, whatever topic one turns to, one finds the essential points well and clearly stated. It has been my experience more than once, after wrestling with a tricky point, to find the conclusion that I have extracted with difficulty from other sources set down in simple terms in *Nuclear and Radiochemistry*.

The title and contents of the book prompt the questions: What is nuclear chemistry? and What is radiochemistry? The claim that the book is "written by chemists for chemistry students" is a valid one, yet of the fifteen chapters, only three deal with specifically chemical topics, and only two others contain sections of any length on chemical subjects. Moreover, the chapter on radioactive tracers has actually been shortened in the new edition.

I first remember the term 'nuclear chemistry' in the annual reports of the Chemical Society for 1935, when it was used to refer to the science of nuclear transmutations, on the analogy between chemical reactions, in which atoms are conserved, and nuclear reactions, in which nucleons are conserved. It is now often used to mean something like "nuclear studies carried out by chemists". Some of the properties investigated in this context undoubtedly belong to the realm of physics rather than chemistry, but chemists do a large share of the work because success depends on preparing pure specimens and on carrying out efficient chemical separations at the end of the experiment.

However, the term is also used in a much wider sense. Coryell, in his foreword to the English edition of Haissinsky's *Nuclear Chemistry and its Applications*, speaks of it including "nuclear reactions, radioelements, radiochemistry, isotope chemistry, radiation chemistry, and tracer applications", and all those fields and more are indeed covered in Haissinsky's book, even though Haissinsky's own definition of nuclear chemistry is merely "the study of the transmutations and transformations of nuclei".

'Radiochemistry' is likewise used in both broad and restricted senses. Originally it referred to the chemical effects of ionizing radiations, but this is now a matter of history only. Later it was applied to the chemistry associated with the natural radioelements, though excluding the ordinary chemistry of thorium and uranium, in which radioactivity played no part. When artificial radioactivity was discovered, the term was of course extended to the new radioactive species. A further extension was to the radiotracer field, in which both natural and artificial radioelements find numerous applications. Many authors still stop at this point, and leave the lively subjects of hot atom chemistry and nuclear chemistry (in the limited sense) largely outside the scope of 'radiochemistry'. Others again treat the subject as if it were primarily a collection of manipulatory and measuring techniques. *Radiochimica Acta*, on the other hand, adopts a more eclectic view—one which I also favour. There seems indeed no good reason why 'radiochemistry' should not include all aspects of the interaction of chemistry with radioactivity, with the sole exception of most of the radiation chemistry aspects, which involve by and large a distinct set of concepts and techniques.

This discussion is relevant to the book under review, because it needs to be appreciated that *Nuclear and Radiochemistry* is primarily a text-book of nuclear chemistry in the restricted sense, and only secondarily a general text-book of radiochemistry. The nucleus itself, nuclear reactions and radioactivity are discussed very fully, since they form the principal subject of investigation in nuclear chemistry, and so are the techniques needed. Other radiochemical topics are treated much more briefly, and very largely from the point of view of the nuclear chemist. In saying this, no criticism is intended, but rather a definition of the scope of this important work. H. A. C. MCKAY

FOURIER THEORY

A Treatise on Trigonometric Series

By N. K. Bary. Vol. 1: Pp. xxiii + 553. 84s. net. Vol. 2: Pp. xix + 508. 105s. net. (London and New York: Pergamon Press, 1964.)

PROF. Nina Bary, distinguished for her contributions to the theory of functions of a real variable, died in 1961, the year of publication of her book on trigonometric series of which this is a translation. Zygmund's much-extended two-volume revised edition of his book on the same topic appeared in 1959, when Prof. Bary's was already in proof, so that we now have two independent and up-to-date treatises, each with much the same aim: to lay firm foundations of the theory and to carry the work, in suitably selected regions, to the frontiers of present knowledge. Both books are intended for the pure mathematician who can claim some acquaintance with set theory and the Lebesgue integral; there is nothing for the applied mathematician or physicist. The total amount of material is about the same in the two books; but Zygmund deals with several topics which Bary does not touch, while she has only two chapters not covered in Zygmund. The difference here is due to the slower pace of the Russian book; Zygmund demands throughout a fairly high level of mathematical sophistication, whereas Bary takes things at a more leisurely pace, particularly in her first volume. The phrase "it is easily seen" has been used, often in a Pickwickian sense, by many authors since Laplace set a bad example; in her preface, Bary protests against its frequent misuse, and has endeavoured to make her text, at least in the first volume, easily readable by the good undergraduate. To some of the longer and more delicate proofs, she appends informal comment to sketch the main lines and to emphasize the critical points of the argument.

After some preparatory analytical matters, a long first chapter of some 170 pages gives a good general survey of the domain, including the Dini and Jordan tests for convergence, the Gibbs phenomenon, Cesàro and Abel summability, Poisson's integral. Chapter 2 deals with the order of magnitude of Fourier coefficients of certain types of function, and Parseval's theorem. The next three chapters take the natural line of examining the convergence of a Fourier series at a point, the uniform convergence of a Fourier series of continuous functions, and convergence in a point-set. Most of this is to be found in the first half of Zygmund's first volume, but the last chapter deals with work by Men'shov on a problem which Zygmund does not touch: roughly, given a function $f(x)$, can it be altered on a set of arbitrarily small measure to give an 'adjusted' function the Fourier series of which will converge everywhere or almost everywhere, or converge uniformly?

Vol. 2 begins with summability processes, the simpler part of the theory of the conjugate series, absolute convergence, sine and cosine series with coefficients which tend to zero, and the remarkable differences which arise when the series is lacunary, having increasingly large gaps. Then there are chapters on the convergence, absolute convergence, and uniqueness of the general trigonometric series: in the main, these topics centre around what can be said about a point set on which the series has a certain specified behaviour. The final chapter deals with another problem of Men'shov's, again not discussed by Zygmund: this concerns the representation of a function by a summable trigonometric series, arising from work by Lusin and Privalov which showed that if a function is finite almost everywhere (in the basic 2π interval) then a trigonometric series can be found which is summable to the function by the Riemann, Poisson or Cesàro methods.

The techniques used are on the whole not so advanced as those which Zygmund draws on, so that a good deal of his second volume lies outside the range of Bary's book. The student thinking about research in this field might well begin and go a long way with Bary, turning to Zygmund

for the sharper weapons likely to produce a deeper penetration.

There are some infelicities of expression, possibly due to the need to keep the translation close to the original. In some places, it is said that an assertion "cannot" be true when what is meant is that it "need not" be true: this distinction is important, and blurring it may confuse the novice. But in general Mrs. Mullins has coped well with a gigantic task.

T. A. A. BROADBENT

ERGONOMICS

Ergonomics

Man in his Working Environment. By K. F. H. Murrell. Pp. xiv + 396. (London: Chapman and Hall, Ltd 1965.) 63s.

ERGONOMICS: Man in his Working Environment provides an important link between scientific research and industry. It is a text-book both for investigators in the basic sciences concerned with the practical application of their research, and for industrialists and designers who appreciate the importance of the human factor in maximizing industrial efficiency.

Ergonomics has been defined as "the scientific study of the relationship between man and his working environment", but Mr. Murrell has extended the term 'environment'. The key *motif* of ergonomics is that of fitting the work situations as a whole to the man on the basis of scientific knowledge, including knowledge of human physiological and psychological capacities. This is called 'human engineering' in the United States. It is an interdisciplinary applied science relating principles derived from the basic sciences to work design, the control of physical environment factors and the mode of work organization.

With more and more semi-automatic and automatic processes being introduced into industry, the contention is that when equipment is intended for human use, it should, so far as possible, be designed to give effect in a man-machine unit, with the man complementary to the machine and the machine complementary to the abilities of the man. While physical stress has tended to be reduced in modern industry, the shift of emphasis from man as 'doers' to man as 'controllers' has tended to increase psychological stress. Stress can lead to inefficiency and reduced output, through failure to match the requirements of the task with the capacity of the operator. Again, the contribution of ergonomics to work design is invaluable when technical change makes it necessary for operators to move on to jobs which may be variants of their old jobs or entirely new.

As a dual text-book for scientists and industrialists the book is well designed. Part 1 outlines salient data from physiology, anatomy, psychology, etc., while Part 2 deals with practical ergonomics and gives examples of the application of ergonomic principles in work design and manpower utilization. The book is easy reading; technical and scientific jargon having been largely avoided. Mr. Murrell points out that while there is a large body of data in scientific publications which is relevant to industry, there is need for some translation to put this to work. He contributes materially to such a translation, and this publication contains an extensive reference section to his material.

The chapter on the design of seating provides an example of the universality of ergonomic contribution to human well-being. The importance of good seating design is becoming more widely recognized. While considerable research has been done in seating design, surprisingly little of that research has been put into practical application. This chapter sets out the requirements of good seating as ascertained from research, summarizes the relevant anthropometric data and gives practical advice for seating-manufacturers.

Significantly, Mr. Murrell's final chapter deals with the necessity of taking account of ageing in the interests of assuring the maximum efficiency of available manpower. The importance of this is underlined by the fact that more than 50 per cent of the male workpower in British manufacturing industry is already over the age of forty. In certain circumstances efficiency can be affected by the concomitants of ageing from as early as thirty-five. Yet industry has shown little interest in research on ageing in relation to occupation. In our present demographic circumstances there is need to retain or engage older workers. But industrial gerontological research emphasizes the basic necessity of appropriate work-changes, even from the middle-age, if older manpower is to be used to the best effect. The author relates age-indicated work-change to that resulting from technical developments. In both, the use of ergonomic principles would result in a better matching of job demands and physiological and psychological capacities. This may be either through a shift to an alternative job, that is change 'of' the job, or some modification of the work demands, that is change 'in' the job. The latter alternative gives greater opportunity for the continued use of the previously acquired skills and experience.

It is evident that ergonomics can make an important contribution to the more efficient and more considerate use of manpower. This book will also be of interest to non-specialists who wish to be conversant with the relationship between science and its practical application in the modern world

C. E. FLEMING

REGULATION OF GROWTH

Adaptive Growth

By Prof. Richard J. Goss. Pp. 360. (London: Logos Press, Ltd., in association with Elek Books, Ltd. Distributed by Academic Press, London and New York, 1964.) 70s.

THIS book will be welcomed by all biologists and pathologists interested in vertebrate development, for it fills a gap in the bibliography of this subject. Another attraction is that it is written by a single author, who has something definite to say and who says it well.

Prof. Goss has set out to explain diverse kinds of post-embryonic growth in terms of a unifying hypothesis, namely that the regulation of growth is governed by the functional demands of the organism. He is fully aware of the teleological overtones of the word 'demand' and carefully avoids them in his attempt to elucidate the mechanisms which control the homeostasis of growth. The characteristics of different types of developmental phenomena, such as the local control of wound healing, or the systemic mediation of compensatory growth, are interpreted as adaptive responses determined by the function of the organ concerned and the nature of the stimulus. Normal growth is discussed in terms of cell turnover, different modes of proliferation of cell populations are classified, and ageing—"the body's homeostatic depreciation"—in some tissues is briefly reviewed.

Nearly half the chapters of this book are devoted to an analysis of compensatory growth which is exhaustively considered on gross, histological, cellular and molecular levels. Evidence of the action of humoral activators and inhibitors is critically examined. The liver and haematopoietic system predominate in this analysis, as the majority of investigations have been concerned with these tissues, but all other organs which show compensatory growth are dealt with. The adaptive role of the pituitary-thyroid system could have been more fully described, particularly the functional significance of the relay system.

No attempt has been made to review growth in all vertebrate groups. No data on fishes or reptiles are included, and little on birds. Perhaps this is because little space has been devoted to morphogenetic regeneration

(apart from an interesting chapter on amphibian lens regeneration) although the author himself has made outstanding contributions to this subject. He does, however, briefly mention Singer's and Thornton's investigations, commenting on the significance of the role of nerves in limb morphogenesis.

The chief task of this monograph is to re-define all growth phenomena according to functional ideas. As the author points out in his preface: "It has become fashionable to disregard functional considerations in favour of mechanisms by which the regulation of tissue mass might be an end in itself. Consequently, much of to-day's research is predicated on the assumption that humoral agents are responsible for adjusting the sizes of organs to certain predetermined dimensions".

While the author does not deny the participation of humoral agents in the control of mitosis of many tissues, he postulates that they are primarily dependent on the physiological demands of the particular tissue. Thus the stimulation of erythropoiesis is mediated through the same regulatory mechanisms whether the initial functional insufficiency was due to loss of blood or reduced oxygen in the environment. Likewise the mechanisms controlling epidermal hyperplasia are the same in wound-healing and the growth of calluses. This interpretation is controversial. It is not the view, for example, of Prof. Bullough, whose ingenious experiments on mouse epidermis and whose theory of mitotic inhibition by chalones are reviewed by Goss.

Moreover, there seems to me to be a deeper contradiction between a 'chalones' theory of mitotic regulation and the functional demand theory. Prof. Swann, a proponent of the functional demand theory himself, has pointed out that mitosis is a form of differentiation in requiring specialized (but not tissue-specific) protein synthesis which must therefore be antagonistic to tissue-specific synthesis, and Glinos has suggested that functional overload of tissue-specific synthesis (in the liver) switches the synthetic machinery of the cell to elaborate mitotic proteins. The chalone theory recognizes the antagonism, but reverses the action of the products of differentiation (chalones) so that they inhibit mitoses, or, as recently stated in more contemporary terminology, the concentration of a chalone has an effector-like action "which determines whether the 'mitosis-operon' or the 'tissue-operon' is active"¹. In renewing cell systems, such as epidermis or blood cells, a single stimulus could derepress the synthesis of both mitotic proteins and tissue proteins, since proliferation and differentiation represent separated compartments of the cells' life-histories. In expanding cell systems, however, where there is no distinction between stem-cells and functional tissue (for example, liver), partial ablation will cause a substantial rise in the mitotic index of the remaining tissue just at the time when the functional demands for tissue-specific products are greatest (though it is not yet certain whether an increase in the tissue-specific protein synthesis per cell occurs simultaneously). While Prof. Goss reviews in some detail the various theories of mitotic control and the data supporting them, he does not clearly define this conflict between immediate and long-term homeostasis of functional activity, which must occur if mitosis and differentiation are competitive or mutually exclusive. If products of differentiated tissues normally inhibit mitosis and further tissue-specific synthesis, then a fall in their concentration following partial ablation will promote both activities, though it remains to be explained how different cells in an expanding system are allocated to the alternative pathways.

Since this monograph represents a virtuoso performance over a wide repertory, it is not surprising to find occasional factual inaccuracies and interpretative inconsistencies. Thus on p. 88, Prof. Goss is of the opinion that "cell migration is antagonistic to cell division", stating that "Abercrombie and Ambrose suggest that until the motile cells in a healing wound again become station-

ary as a result of contact inhibition, their mitotic propensities are temporarily suspended". In fact they suggest the opposite, which Prof. Goss himself corroborates five pages later when discussing Harding and Srinivasan's observations on small wounds in lens epidermis.

Prof. Goss includes a chapter on maternal-foetal relationships in which he reviews the poorly understood interactions between homologous organs in this "special case of parabiosis". There is also an interesting chapter on allometry in which the author discusses the functional, histological adaptations in some organs relating to the size of different species, and the adjustments in size which may occur following transplantation of organs. In a delightful account of the allometric relationships of urodeles varying in ploidy, we see that although cell size varies according to the number of chromosome sets, the size of gross and histological structures is constant, indicating that it does not matter how the chromosomes are packaged, their total number being the controlling factor. This can lead to certain developmental dilemmas, such as when the size of an 'organ' approximates to the size of the diploid cell. Triploid erythrocytes can pass through capillaries of normal (diploid) diameter (by change in shape, which gives a clue as to how their shape is controlled), but the single pair of Mauthner's cells cannot remain proportional both to ploidy and brain size.

Prof. Goss mentions Fankhauser's discovery that triploid salamanders are less intelligent than diploids, and he states that "the quality of the central nervous system cannot be improved by increasing the size of neurones at the expense of their numbers". It is disappointing that Goss does not actually pose questions about the lack of compensatory growth of the brain, though he does incidentally provide most of the answers! There are several unsolved problems concerning the different sizes of neurones. Whereas hypertrophy of particular nerve cells occurs, usually as a consequence of functional activity, neuronal hyperplasia is not known. Goss prefers to regard mitotic incapability as an adaptation serving to prevent disruption of organized cell communities rather than an unfortunate consequence of specialized differentiation. It is the function of the cell, not its "degree of specialization", that governs its ability to divide. Neither is it functional in the case of nerves and muscles to maintain 'mitotic competence' by recruitment from undifferentiated stem-cells.

Prof. Goss brings a fresh and firmly biological approach to his analysis of regulatory phenomena in growth. His controversial ideas should lead to lively discussions and penetrating research during the next few years.

MICROLEPIDOPTERA UNDER THE MICROSCOPE

Catalogue of the Type Specimens of Microlepidoptera in the British Museum (Natural History) described by Edward Meyrick

By J. F. Gates Clarke. Vol. 5. Pp. 581 (283 plates). (London: British Museum (Natural History), 1965.) 300s.

BIOLOGISTS do not often realize the immensity of the task still to be undertaken and the vast amount of published work needed before even half the species of the world can be named even by specialists. Much of the work was (and a considerable amount still is) done by expert amateur entomologists. Meyrick's position as an amateur entomologist was perhaps unique because of the extent of his work. Although well up to the standards of his time, his failure to illustrate his new species created a world problem. He first published descriptions of new species of microlepidoptera in 1886 when he was a schoolmaster in New Zealand, and he gradually came to dominate their

study after his return to England. He retired in 1914 after many years teaching classics at Marlborough College. Specimens of microlepidoptera were sent to him by collectors and museums from all parts of the world, but he retained in his collection, which is now in London, only about a third of the types. By the time of his death in 1938 he had published descriptions of about 15,000 new species (catalogued in Volume 1).

Dr. Gates Clarke became an authority on the microlepidoptera through his work for the United States Department of Agriculture and the Smithsonian Institution, and found some years ago that further taxonomic progress was impossible until Meyrick's species had been re-examined. He then worked for some years at the British Museum (Natural History) and the Trustees gave him permission to dissect Meyrick's types. The abdomens of the 5,000 moths were carefully removed, softened, dissected and mounted on microscope slides. This has for the most part been carried out with commendable skill, but it would be interesting to know whether the large numbers of Cosmopterygidae male genitalia were mounted sideways from choice, or whether their symmetrical arrangements presented peculiar difficulties.

Volumes 1 and 2 of this work were published as long ago as 1955 and it is very much hoped that the final one or two volumes will soon be completed. This, the fifth volume, dealing with moths of the families Timyridae, Hyponomeutidae, Ethmidae, Metachandidae, Cosmopterygidae, Walshiidae, Blastodacnidae and Scythridae, contains 283 half-tone plates some of which include as many as 15 illustrations. For each species there is a photograph of the wings of one side of the type specimen and sometimes a picture (which gives rather little detailed information) of the head and its associated sense organs. If the species is the type of a genus there is also a clear drawing of the wing venation. Photomicrographs of dissections of the genitalia of the types provide a much-needed supplement to Meyrick's original description. The quality of the photographic illustrations is almost uniformly good, so that in spite of difficulties with depth of focus they are almost as useful as good drawings would be.

Apart from a very few instances where the author synonymizes two species, the text consists of little more than a legend for the illustrations and the reference to the original description of the species concerned. Lectotypes are designated when needed and Meyrick's occasional errors in determining the sex of his specimens are corrected.

When this series of volumes is complete, the stage will be set for the next advance. This will be the revision of genera, including species described by many authors. That there is much to do is clear even from a superficial study of the diversity of form in such genera as *Lecithocera* and *Ethmia*. Dr. Gates Clarke has wisely not tried to do two things at once, for the present work is already large and expensive. The speed with which these much-needed revisions come will depend very largely on the funds available for this basic kind of work in museums and universities. The Trustees of the British Museum (Natural History) already publish a very substantial amount, but publications like this are, unfortunately, still far too rare. Of the hundreds of thousands of type specimens in the museums of the world a surprisingly high proportion must still await critical re-examination. Experience suggests that the original descriptions have been misunderstood in at least one-tenth of the cases. Many of the changes in the names of animals which so baffle the non-specialist are caused by the correction of these old mistakes of identification.

Dr. Gates Clarke is to be congratulated on performing this basic and useful task, and the staff at the British Museum (Natural History), especially Mr. J. D. Bradley, who has assisted in the work at every stage, will earn the thanks of the many specialists in various parts of the world who will find this work indispensable.

G. C. VARLEY

Man's Place in the Island Ecosystem

A Symposium. Edited by F. R. Fosberg. Pp. vii + 264. (Honolulu, Hawaii: Bishop Museum Press, 1963.) 8 dollars.

WHEN the late Sir Arthur Tansley in 1935 introduced the term ecosystem and later defined it as "a unit of vegetation considered as a system . . . includes not only the plants but also the animals habitually associated with them", it may be doubted whether he envisaged man as the most important animal concerned. Yet this is the logical conclusion, and where better to study the problems involved than among the numerous and varied islands of the vast Pacific Ocean? An island is a clearly defined areal unit; in the Pacific there is every stage from the uninhabited coral islet to the crowded sophisticated human atmosphere of the United States' fiftieth State. Under the Humid Tropics programme of Unesco, a symposium was arranged to take place at the tenth Pacific Science Congress held in the University of Hawaii at Honolulu in August 1961. It was very efficiently organized by Dr. F. R. Fosberg (Washington), aided by his able lieutenant, Dr. Marie-Hélène Sachet, and he contributes the short introductory paper on the ecosystem concept.

The major criticism must be that too much was attempted in the time allotted. Each of the thirteen papers is of the nature of an *ex cathedra* statement and each was followed by a comment by a 'discussant'—limited to 3 or 5 min, despite the fact that he might have been flown half-way around the world to take part. It was soon clear that no time would be available for discussion; in a few cases a question or two after the discussant had spoken. Many of the big names in the ecological field from all over the world are there—Marston Bates (Michigan), Pierre Gourou (Brussels), G. Mangenot (Paris), Irene Taeuber (Princeton), William L. Thomas (California), Kenneth Cumberland (New Zealand)—among the contributors; J. A. Steers, H. E. Maude among discussants; while a distinguished audience is revealed by simple questions from Paul Sears and C. F. A. Pantin. The task of a general summing up was left to Oskar Spate (Canberra).

The symposium is a landmark in the present development of thought. The ecosystem was the concept of a botanist mindful of the interaction of plants and animals and of the significance of the complex environment with its various physical factors. Here the influence of man brings in the physical and human geographer with the concept of human ecology fitting into the whole. The time to absorb the several contributions was lacking in Honolulu; this comprehensive report allows time for the proper and careful study of a series of papers of the highest value and significance. The sequence is logical—from physical environment and marine influence to the nature and evolution of the biota, the reciprocal man-nature relationship, the pattern and varied nature of human influence and culture systems to the practical issues of the present problems of human pressure and demographic instabilities. This is an essential volume for every serious library.

L. DUDLEY STAMP (Discussant)

A History of Parasitology

By W. D. Foster. Pp. vi + 202. (London and Edinburgh: E. and S. Livingstone Ltd., 1965.) 35s.

THIS is a well-written and interesting book and I gained much pleasure and information from it. It is the first account of the history of parasitology written in English, and a book that has long been needed.

The author provides, in his first chapter, a succinct account of the growth of parasitology from ancient times. In succeeding chapters, in order to illustrate the basic discoveries of parasitology, he outlines the history of our knowledge of a series of animals parasitic in man.

He begins with the trematodes, and discusses the liver fluke, *Fasciola hepatica*, and the schistosomes, which cause

bilharziasis, which is still one of the major diseases of man and at present the subject of a campaign organized by the World Health Organization. Four nematode types are then discussed, namely the hookworms, *Trichinella spiralis*, the Medina worm (*Dracunculus medinensis*), and *Wuchereria bancrofti* (a cause of filariasis). He next considers, in a separate chapter, the parasitic Protozoa. In the chapters that follow he treats the trypanosomes, *Entamoeba histolytica*, the cause of amoebic dysentery, and those other Protozoa, the babesias, which cause serious diseases of cattle and other farm stock. A final chapter brings the history up to about the year 1920, when parasitology became well established as a branch of biology.

This plan has certain advantages, but it does tend to direct attention to the animals parasitic in man only, and some readers will wish that more attention had been given to the achievements of veterinary parasitologists. It is true that their work on the babesias is discussed, but more space might have been given to the part played in the development of parasitology by co-operation between the veterinarians and workers concerned with diseases of man. Moreover, a chapter on the social and economic effects of parasitic animals and the devastating effects of some of them on the food supplies of the world would not have been out of place, for there is much evidence that animals parasitic in man have, through their social and economic effects, influenced appreciably the course of human history. Diseases caused by them have, for example, greatly influenced, if they have not actually determined, the outcome of wars. But themes such as these were no doubt outside the author's intention, which was, he explains in his preface, "to give an accurate account of the basic discoveries of parasitology . . . at a level comprehensible to the non-professional parasitologist". In this general aim he has certainly succeeded. The book will be read with pleasure and profit by all who are interested in the subject.

G. LAPAGE

Histologie und Mikroskopische Anatomie des Menschen

Von Dr. W. Bargmann. 5. überarbeitete Auflage. Pp. xvi + 856. (Stuttgart: Georg Thieme Verlag, 1964.) 72 D.M.

THE fact that Dr. Bargmann's book is, after fifteen years, already in its fifth German edition, and that the second Spanish edition is in preparation, speaks for the author's thoroughness in revision and his desire to keep up with recent developments. The text is based on a correlation of histology with physiology, biochemistry and submicroscopic morphology on one hand, and where applicable to pathology on the other. The text is divided into two parts. The first deals with general cytology and a descriptive exposé of the tissues: epithelial, supporting, muscular and nervous.

The second part considers the organs and organic systems: locomotor, circulatory and defensive, internal, secretory, digestive, respiratory, urinary, sexual, cutaneous, sensory, and central nervous systems. The text is lucid and integration of the different disciplines is excellent although some might find a more extensive discussion of tissue culture morphology of advantage. Literature references are ample and not confined to German publications. The illustrations are of excellent quality, but, as they are not indicated in the index, are sometimes hard to find if a particular one is sought. Another criticism, which applies to most publications, is that magnifications mentioned do not indicate whether they apply to the finished product or are applicable to some previous stage in their production. Both reference and subject indexes are adequate with the aforementioned reservation.

In conclusion this book is of general interest and, because of the illustrations, might even prove useful to workers who have only a limited knowledge of German.

G. SANDER

Theory of Crystal Dislocations

By Prof. A. H. Cottrell. (Documents on Modern Physics.) Pp. ix + 94. (London and Glasgow: Blackie and Son, Ltd., 1964.) 32s. 6d.

THIS little book (also available in paper-back form) is a kind of *vade-mecum* for dislocationists. It deals with the basic theory of dislocations, and consists mainly of the notes prepared for Prof. Cottrell's lectures to the 1956 summer school of the University of Grenoble at Les Houches. Some measure of the extent to which this theory has now been incorporated into the accepted physical scheme is provided by the fact that only minor changes were necessary when the manuscript was prepared for publication six years later.

It is perhaps unnecessary to add that this rather satisfactory situation does not extend to the complex many-dislocation problems which are encountered in plastic deformation. Developments in the theory of deformation, and in the experimental observation of dislocations by high-resolution techniques, are mentioned briefly in a series of very short notes added to the original manuscript. Although these additions were completed as recently as 1962, they have inevitably dated much more rapidly than the basic theory; the 'jog theory' of work-hardening, for example, is no longer current.

The book is written with Prof. Cottrell's usual clarity, but it should be emphasized that it is not a text-book from which to approach the basic theory for the first time. Its main use will undoubtedly be as a desk-book for quick ready reference, or as a companion of such slender dimensions as not to deter the aeroplane traveller. It is a great convenience to have so many useful results gathered together in compact form, and it may seem ungrateful to ask for more. However, there have been important developments in basic theory in the past few years, dealing, for example, with the stress fields of various types of dislocation aggregates, or with the theory of continuous distributions of dislocations. If Prof. Cottrell could find time to add these to a future edition, the value of the book would be even greater.

J. W. CHRISTIAN

Molecular Orbital Theory

By C. J. Ballhausen and Dr. Harry B. Gray. (Frontiers in Chemistry.) Pp. ix + 273. (New York and Amsterdam: W. A. Benjamin, Inc., 1964.) 9.90 dollars.

THIS book is divided into two approximately equal parts, the first being a text of atomic orbitals using the LCAO approach, while the second part is a collection of previously published papers on the subject. A very simple and short exposition is given of the basic concepts of the LCAO theory, which leads into a group theoretical section on the uses to which these simple concepts may be put. These include symmetry consideration electronic states and hybridization. The types of possible bonding systems are discussed and the results applied to selected diatomic, triatomic and a few of the more simple polyatomic molecules. Finally, the theories developed are applied to more complicated polyatomic molecules making use of ligand field theory. The book is written in a simple manner with the result that the reader is sometimes left with the impression that the stage of knowledge of molecular theory is more advanced than is the case in reality. The illustrations are not only well done but are also so positioned in the text that they are extremely useful to those readers who are not very conversant with the more mathematical form of presentation. The choice of papers in the second part is in some cases a little surprising, but some very useful information has been collected together, making the book valuable as a reference for the reader interested in making molecular calculations.

E. W. T. RICHARDS

The Evolution of the Bristol Channel

By F. J. North. Third edition, revised and enlarged. Pp. vii + 110 + 14 plates. (Cardiff: National Museum of Wales, 1964.) 15s.

OVER a period of many years Dr. North has done much to interest the layman in geology, particularly in South Wales. In the third edition of *The Evolution of the Bristol Channel* one of his books is once more brought up to date, incorporating much recent work in this area. A historical introduction precedes a simple account of the geological processes of erosion, transport and sedimentation, and earth movements; and this is followed by a concise geological history of the region, with particular reference to the Welsh coast. Useful palaeogeographical maps and a geological time scale (the latter unfortunately not brought up to date) accompany accounts of the structure of the Welsh coalfield and of the geological reasons for the distribution of the mines. Similarly a description is given of how the formations exposed on the coast of South Wales control the form of the coast-line. The origin of the South Wales drainage pattern, the evolution of the Bristol Channel since its appearance in Pliocene times, the Recent changes in sea-level, the appearance of man, the accretion of sand dunes, and the great flood of the Wentloog Level in 1607 are among the many topics dealt with in an interesting manner. The plates and diagrams usefully supplement the text, though the standard of reproduction is not high. Visitors to the South Wales coast and the local inhabitants are fortunate in having available this very readable account of the local geological history.

A. R. MACGREGOR

Tizard

By Ronald W. Clark. Pp. xvii + 458 + 16 plates. (London: Methuen and Co., Ltd., 1965.) 50s. net.

SIR HENRY TIZARD is still freshly remembered by many who worked with him or were associated with him in one or more of his varied activities. In the relatively short time since his death numerous tributes have been paid to his work, notably by Prof. P. M. S. Blackett and by Prof. R. V. Jones in Tizard Memorial Lectures, in Sir Harold Hartley's memoir for the Chemical Society, and by Sir W. S. Farren and Prof. R. V. Jones for the Royal Society. Nevertheless, there is a place for Mr. R. W. Clark's book, in which he has made full use of his access to unusually large collections of papers.

With one reservation, Mr. Clark has given us a well-balanced account of Tizard's life and work which does full justice to Tizard's real achievements. The reservation relates to the chapter on Tizard's post-war years as chairman of the Advisory Council on Scientific Policy and of the Defence Research Policy Committee, which scarcely conveys the significance of his positive achievements or the magnitude of his own contribution to the complex problems of the relations between science and Government. Mr. Clark, moreover, has avoided being drawn into personalities of the argument that has stemmed from Sir C. P. (now Lord) Snow's lecture on that theme, and his book points to most of Sir Henry's activities in the field of education. Its value is enhanced by a careful bibliography and references to most of Sir Henry's published papers. There is an error on p. 369, when a long letter to Sir Alan Barlow is attributed to Sir Henry himself instead of Sir Thomas Morton—an error which has since been rectified by Mr. Clark, who notes that the views expressed in it are substantially those of Sir Henry himself.

If the book is one to be studied by all who are concerned with the intricate problems of science and Government, it can scarcely be put down by a British reader without some sense of shame for the way in which Sir Henry was treated by the British Government. The exploitation of the scientific adviser moving in and out of the Civil Service is a reproach which we should be at pains to avoid in any structure established for civil science.

RECENT DEVELOPMENTS IN COSMOLOGY*

By PROF. F. HOYLE, F.R.S.

Professor of Astronomy and Experimental Philosophy, University of Cambridge

I SHALL start from the observed shift of the spectrum lines of galaxies interpreted in terms of the expansion of the universe. The red shift implies that distances between galaxies, measured with an imaginary ruler for example, increase with time. An immediate question is whether the universe was denser in the past than it is to-day. If so, how much denser was the universe?

A definitive answer to this critical problem could be obtained in principle by observing the state of the universe in the past. This is possible because of the finite speed of light. We do not observe a galaxy as it is now but as it was at the moment the light started on its journey. In the case of very distant galaxies the light started several billion years ago, so we have direct evidence of the state of affairs several billion years ago. All that need be done, again in principle, is to observe the density of galaxies as it was a few billion years ago and to compare it with the density in our immediate neighbourhood. This would be a direct way of settling the density problem. This indeed was the way in which Hubble tried to settle it more than thirty years ago. He failed to do so because of the extreme difficulty of making a fair count of distant galaxies. The tendency is to count the brighter galaxies but to miss the fainter ones. Since Hubble's attempt nobody has had the hardihood to make a direct assault on the problem by attempting to count galaxies.

Ryle and his associates have counted radio sources instead of galaxies, and here the result has turned out to be much more clear-cut, at any rate so far as the counting process itself is concerned. The difficulty with radio sources is that we are still far from sure exactly what it is that is being counted. Developments in the past two years, the discovery of the quasi-stellar sources in particular, have shown the situation to be more complex than it was at first thought to be. The indication of the radio counts is that the universe was more dense in the past than it is to-day. However, further knowledge is needed concerning the nature of the radio sources before this conclusion can be regarded as definitive.

If the quasi-stellar objects are truly cosmological a great deal becomes pretty well settled. Imagine an object of fixed intrinsic brightness to be moved to increasingly great distances. Two things will happen. The apparent luminosity of the object will decrease and the red-shift of the spectrum lines will increase. A theoretical relation between these quantities can be determined for any specified cosmological theory. The relation is different in different theories, so that in principle it would be possible to distinguish between one cosmological theory and another if we could experiment in this way with a standard object of fixed brightness. Unfortunately it is impossible to move a single object to increasing distances; so the astronomer must rely on similar objects just happening to lie at different distances. The question then arises of how sure we can be that the objects are really similar to each other. Massive galaxies do seem to be quite remarkably similar, but the theoretical differences we are looking for are rather slight in the case of galaxies. This is because galaxies, even the brightest galaxies, cannot be observed far enough away for the theoretical differences to be more than slight. At greater distances the theoretical differences become much more appreciable, however. The technical problem is that of photographing spectrum lines when the light intensity is very small. What is needed is more light. It is here that

the quasi-stellar sources are of critical importance. Accepting for the moment that the red-shift of the spectrum lines in these sources is cosmological in character, the quasi-stellar sources are brighter than the most massive galaxies by about four magnitudes, a factor of about forty.

At present, red-shift measurements are available for about fifteen quasi-stellar objects. The shifts are dimensionless numbers given by dividing the wave-length shift of any spectrum line by the laboratory wave-length of the same line. The result is the same for all lines. The measured values range from quite small values, for example 0.16 for 3C 273, up to the enormous value of 2 for the source 3C 9. The theoretical differences become quite large for red-shifts as great as this, so that a distinction between different cosmological theories should be straightforward once a sample of the order of a hundred quasi-stellar objects has been obtained. The present indication based on the small sample of fifteen is that the universe has expanded from a state of higher density, although the statistical scatter in the sample is large enough to be comparable to the effects that are being looked for.

For spectral shifts as large as two, the Lyman- α line is displaced from the unobservable ultra-violet into the blue, at about 3700 Å. It is possible to look for a continuum on the blueward side of Lyman- α . This continuum is subject to absorption by neutral hydrogen atoms in intergalactic space. A very small density of neutral atoms would be sufficient to absorb out the light completely. Schmidt's observation of 3C 9 shows the continuum to be present but to be weakened, that is, to be lower than the continuum on the redward side of Lyman- α . The implication is that intergalactic gas, if it exists, must be hot, perhaps above 10^6 °K. The weakening of the continuum is rather strange, for in a sensitive situation like this one would expect either the continuum to be essentially unweakened or to be absent. The intermediate case seems *a priori* unlikely, since it depends on a closely defined value of the hydrogen density. It is rather in the nature of a coincidence that the density has this critical value.

These remarks are all subject to a cosmological interpretation of the red-shift of the spectrum lines of the quasi-stellar objects. If much smaller, fainter objects were fired out of our own galaxy, or out of some neighbouring galaxy, with speeds close to light the same red-shifts would be observed. Can we be sure that such a 'local' interpretation is wrong?

Even though on a 'local' hypothesis the quasi-stellars are much less spectacular objects, the total mass involved in all such objects must be as high as $10^6 M_{\odot}$, or perhaps even more. For such a quantity of matter ejected at speeds close to light, the kinetic energy must be comparable with the rest mass energy, 10^{60} ergs. This is of a similar order of magnitude to the energy involved in the outburst of a major radio galaxy. The energy in the latter case is also in the form of particle motions. The difference is that the particles in the radio galaxies have been thought of in the past as occupying large volumes, not as being condensed into compact objects. However, we now have to ask whether a radio galaxy may not eject compact pieces as well as diffuse clouds of high-speed particles.

Radio galaxies do not eject their material with an initial isotropy. The typical pattern is of two centres of radio emission on opposite sides of a galaxy, with the two centres and the nucleus of the galaxy more or less collinear. To me personally, this has always suggested that an object in the nucleus of the galaxy separates violently into two

* Substance of an Evening Discourse delivered on September 6 at the Annual Meeting in Cambridge of the British Association for the Advancement of Science.

pieces with a large relative motion. The collinear property then follows from conservation of momentum. Exactly the same phenomenon is observed in the quasi-stellar source *MH* 14-121, two regions of radio emission on opposite sides of, and collinear with, a centre of optical emission. The possibility must be considered that a cascade process is involved. An initial object in the centre of a galaxy breaks violently into two pieces. Later, each of these pieces breaks into two further pieces; and so on. As the cascade develops, and as the objects spread out from the parent galaxy, an approximation to an isotropic situation would then gradually develop.

From independent evidence it has been suggested that an explosion occurred in the nucleus of our own galaxy about ten million years ago. If the quasi-stellar objects emerged in this explosion, as Terrell has suggested, the brightest of the objects, *3C* 273, would now be distant about 0.5 million parsecs, about one-thousandth of the cosmological distance. The optical emission, instead of the enormous cosmological value of 10^{46} ergs sec⁻¹, would be 10^{40} ergs sec⁻¹. The burning of some 300 solar masses of hydrogen gives sufficient energy to supply such an output for as long as ten million years. Since the mass of *3C* 273 could be set as $10^3 M_{\odot}$ there would seem to be no difficulty in explaining the optical output. The kinetic energy of *3C* 273 would then be $\sim 10^{56}$ ergs, about one order of magnitude less than the total energy of the galactic explosion, as estimated by Burbidge and Hoyle. The masses of other quasi-stellar objects can be set lower than *3C* 273, because *3C* 273 is intrinsically considerably brighter than the others, at any rate for the sources so far observed. Setting $10^3 M_{\odot}$ as the mass per object, and taking the mean speed as half the velocity of light, the kinetic energy per object is comparable with that of *3C* 273. The total energy estimated by Burbidge and Hoyle, 10^{57} ergs, would provide only for ~ 10 objects. It would seem therefore that either Burbidge and Hoyle underestimated the violence of the galactic explosion, or an energy difficulty arises.

The same difficulty does not arise in the case of the galaxy *NGC* 5128. This is a nearby massive elliptical, distant about four million parsecs. At least one major outburst is known to have occurred in the nucleus of this galaxy within the past ten million years. The probability must also be considered that both *NGC* 5128 and our galaxy are involved, with our galaxy contributing the comparatively low-speed objects and *NGC* 5128 contributing the high-speed objects.

These questions can undoubtedly be resolved by observation. Observations leading to size estimates for the quasi-stellar objects are coming along with rapidly mounting impetus. The light from *3C* 273 has been known to be variable in a characteristic time of about ten years. This sets the maximum radius of the optical object at ten light years. In addition, rapid flashes in the light over only a few weeks have been suggested. Largely because the maximum radius would have to be reduced to a tenth of a light-year, or even less, there has been a disposition not to believe this evidence in the case of *3C* 273. On the cosmological hypothesis, how can one have an optical emission a hundred times brighter than the most luminous galaxies pouring out of an object only a tenth of a light-year in diameter? The issue appears to have been resolved by a recent observation of a doubling of the light of a quasi-stellar source in less than a month.

On the radio side, fluctuations from *3C* 273 have been found, first by Dent and more recently by Moffet and Maltby. The radio data set stronger constraints than the optical data, particularly for the cosmological theory. The present state of the argument is that the cosmological theory just survives the existing data. Whether it will continue to do so remains to be seen. My judgment of the situation is that survival for the cosmological theory depends on there being a sharp saturation in the accumulation of fluctuation data, that not much more in the way of fluctuations can be tolerated. If we are already near the

end of the road, the theory will survive and will then probably turn out the correct theory. But if we are still near the beginning of the road, the prospects for the theory will be slight. I would say we have to do with a fifty-fifty situation.

I would like to turn now to quite different issues; but still bearing on the question I asked at the beginning: Has the universe emerged from a more dense state? The kinds of observation I have discussed so far all relate to great distances. Observations can be made in our own neighbourhood which also bear on the problem. I am now going to describe three such observations, together with the related arguments. The three are utterly different in character, illustrating how wide are the issues in cosmology, and how very many phenomena have to be made to fit into a consistent picture.

Recently, Penzias and Wilson have observed a radio background at a wave-length of about 7 cm, which they do not believe to be due to their equipment or to the nearby terrestrial environment. The intensity is between 10 and 100 times greater than can be attributed to radio sources. The suggestion is that the universe has a thermodynamic radiation background corresponding to about 3.5° K. Observations at two other wave-lengths at least are needed to confirm this suggestion. One such observation is now being planned by Dicke at Princeton.

There seems no way in which such a background can be explained in terms of current astrophysical processes. Hence, if we accept the suggestion of Penzias and Wilson, the immediate implication is that the universe must have been different in the past from what it is to-day. Particularly, a higher density is needed to generate the background.

A similar result follows from the entirely different consideration of the helium-to-hydrogen ratio in stars and gaseous nebulae within our galaxy. Determinations of this ratio range from 0.08 to 0.18; and the ratio seems to be just as high in old stars as in most young stars. The ratio to be expected from current stellar activity is only 0.01. So either activity in the galaxy was much greater in the past, or the helium cannot be explained in terms of production from hydrogen through thermonuclear processes within the galaxy. Failure to observe any stars or any object with a low helium content points to the second of these possibilities.

It is possible to show by detailed calculation that, if matter in the universe has emerged from a state in which the temperature was above 10^{10} °K, the helium-to-hydrogen ratio must be about 0.14, a value which falls in the centre of the observed range. However, no values less than a truly universal value should be found. Two independent determinations for the Sun, one from structure calculations, one from observations of solar cosmic rays, give concordant results close to 0.09. This seems significantly below the expected universal value; but further work is needed to establish whether the discrepancy is real or not.

All the lines of investigation which I have mentioned so far point to an affirmative answer to the initial question: they point to the universal density in the past being higher than it is at present. Yet in every case the argument has been fraught with uncertainty. The probability seems against a negative answer, yet the possibility cannot be excluded. Speaking personally, I believe the case for a negative answer would still be arguable if it were not for the third of my three lines of attack. This again is entirely different in character from the helium/hydrogen ratio and from the microwave observation of Penzias and Wilson. I refer to the problem of the origin of elliptical galaxies. In my view, a consideration of this problem points decisively toward the universe having been very much denser in the past than it is at present.

Galaxies have been broadly classified into two types—ellipticals and spirals. There is an incontrovertible argument to show that spirals must have condensed from a more diffuse form. The spirals are rotating. Their angular

oments prevent them from being compressed into more compact forms. The flattened ellipticals have always been supposed to be similarly in rotation, but this has never been properly checked by observation. Because the ellipticals were thought to be in rotation it was similarly supposed that they were formed by a condensation process. This, I am now convinced, is wrong. I believe ellipticals have formed through expansion from a higher density state.

Elliptical galaxies are remarkably amorphous. The star distribution is everywhere smooth. If one measures the surface brightness it is found to behave very nearly as an inverse square law, rising with great steepness towards the centre. The centres possess extremely bright central spots. How sharp these centres really are, how star-like, is impossible to say at the moment, for atmospheric seeing effects smear the central pip into an apparent disk.

Suppose the universe expanded from a much denser state, say $10^{-12} \text{ g cm}^{-3}$, and suppose the gas at the beginning of the expansion was not entirely smooth, suppose there were condensation knots already within it. It appears that such condensation knots can restrain the expanding gas to a degree which can be subject to precise calculation. A knot of mass $10^9 M_\odot$ can restrain a total mass of $10^{12} M_\odot$ within a region of galactic dimensions. A knot of $10^7 M_\odot$ can restrain a mass of about $5 \cdot 10^{10} M_\odot$. The critical point now emerges, that the surface brightness of the resulting aggregation can be calculated (assuming the material forms into stars) and the calculations yield quite unambiguously a law close to the inverse square, in fact just what is observed.

The point I wish to make is that whereas the steep rise towards the centre is expected, and is predicted, by the expansion picture, this characteristic feature of elliptical galaxies cannot, I believe, be understood at all within the condensation picture.

The clinching factor, it seems to me, is that a condensation knot—a memory of the initial dense state—is to be expected at the centre of every major elliptical galaxy. It is these condensation knots that give rise to the phenomenon of the radio galaxy. These are the massive objects which Fowler and I postulated some three years ago. Questions were asked of us at the time as to how our objects ever managed to form. Difficulties of angular momentum were raised. The answer which can now be given is that the objects never formed, in the sense in which the questions were asked. They are relics of a much higher density phase of the universe. They have been there since the galaxies themselves were formed, and in the sense of the radio astronomer they have been smouldering throughout the lifetimes of the galaxies. They are systems which remain at the very edge of stability. Whenever instabilities occur, violent outbursts serve to restabilize them.

Why is my initial question so important? Why make such a fuss about whether the universe has been in a more dense state? Because the present physical theory suggests that there is no limit to how great the density must have been in the past. I use the word 'suggests' because the physical divergence of the density was first demonstrated for a homogeneous and isotropic universe. Divergence also occurs when the isotropic restriction is removed. Does it also occur when homogeneity is removed? I have always believed the answer to this question was also affirmative, but my belief was based more on the failure of those who maintained the opposite to demonstrate their case than on any positive demonstration on the affirmative side. However, progress on the affirmative side has been made very recently, and opinion has generally moved toward the view that the equations of physics contain a universal singularity.

I have always had a rooted objection to this conclusion. It seems as objectionable to me as if phenomena should be discovered in the laboratory which not only defied present physical laws but which also defied all possible physical

laws. On the other hand, I see no objection to supposing that present laws are incomplete, for they are almost surely incomplete. The issue therefore presents itself as to how the physical laws must be modified in order to prevent a universal singularity, in other words how to prevent a collapse of physics.

It was with this background to the problem that several of us suggested, some twenty years ago, that matter might be created continuously. The idea was to keep the universe in a steady-state with creation of matter compensating the effects of expansion. In such a theory the density in the universe would not be higher in the past than it is at present. From the data I have presented here it seems likely that the idea will now have to be discarded, at any rate in the form it has become widely known—the steady-state universe. But let me proceed with the theoretical ideas which have grown out of the notions of twenty years ago, for they may turn out to have a value going beyond the first suggestions.

During the past ten years the struggle has been to invent a form of mathematics operating in the manner customary in physics, namely, starting from an action principle. It was found possible to represent the creation of matter through the introduction of a new field. The manner in which the field was treated was quite normal. What was different from ordinary physics was the motive underlying the investigation, the avoidance of a universal singularity, rather than an experiment in the laboratory. Physicists will introduce a new field at the drop of a hat, if experiments in the laboratory should direct them so; but the physicist is unhappy to do so for any other reason.

Having obtained the mathematical structure of the new field it was found that singularities never occur, quite regardless of whether matter is being created or not. So long as the new field exists there will be no singularity either of the universe or of a local imploding body. In other words, the models available for investigation, the models without singularities, were very much wider than the old steady-state theory. During the past few years it is these other models which have been under investigation. What has turned out?

The simplest case is that in which the new field exists but in which there is no creation of matter. It is then possible to obtain a finite, oscillating universe of the kind that has been sought for so long in the usual theory. The universe alternately expands and contracts. Gravitation causes the reversal from expansion to contraction, while the new field causes the rebound from contraction to expansion.

So far as I am aware, such an oscillating model is in satisfactory agreement with all available data. The model is less dull than it seems at first sight, for it contains the possibility of some carry-through from one cycle to the next. Suppose the universe as we observe it eventually stops expanding. Suppose it falls back to a state of comparatively high density, a state in which stars are evaporated, a state in which even the nuclei of heavy elements are disrupted, a state from which matter emerges with the helium-to-hydrogen ratio I described before, about 0.14. In the state of high density things will not be quite uniform. Because of the existence of galaxies, and of clusters of galaxies, there will inevitably be some departures from uniformity. These departures will form the condensation knots round which a new generation of galaxies will form. Thus the condensation knots of which I spoke at an earlier stage are not merely random perturbations. One generation of galaxies acts as the seeds for the next generation. Magnetic fields will also persist from cycle to cycle.

There are two objections to this model. The new field is without sources. It is introduced *ad hoc*, along with the matter. There is never any coupling between the matter and the field. Then there is the subtle, but I believe the correct, objection that a series of oscillations must eventually damp out. Unless dissipative processes are precisely zero,

which seems unlikely, the amplitude of the oscillation will gradually die away and the universe will come to rest in an intermediate static state.

For these reasons it is of interest to examine the models with creation of matter, noticing there is no specification from theory as to what the density must be in the steady-state situation. In the past the density was set empirically, by requiring it to be equal to the present-day density. Perhaps this step was wrong. Perhaps the true steady-state density should be very much higher.

During the past year, Dr. Narlikar and I managed to investigate a possibility which had previously proved too difficult to handle, the case in which there are departures from homogeneity, the case in which there are fluctuations from one region of space to another. To our surprise we found that under certain conditions the creation of matter could fall away in a localized region, and that if it did so the region would break into a series of oscillations of a kind that were closely analogous to the oscillations I have just been describing. In the former case we had oscillations of the whole universe, but of a universe of finite volume and finite mass. In this new case we have oscillations of a finite region of an infinite universe. From the point of view of an observer living in such a region it would be difficult to tell the difference. The oscillations would eventually damp away, but in this second case there would simply be a return to the steady-state condition. In this second case there will be many localized oscillating regions, not merely one. The regions will not in general be

in juxtaposition with each other; they will usually separated like islands in an ocean: and, like islands, they will be of different sizes and the amplitudes of their oscillations will be different.

I have already mentioned the philosophy of the physicist that the whole of physics is discoverable in the laboratory. What has been discovered is a remarkable mixture of elegance—invariance properties for example—and ugliness, the fine structure constant being 137 . . . for example. The properties of matter depend critically on the dimensionless numbers of physics, as well as on the structure of the laws. One can take three views on the dimensionless numbers:

(1) They just happen to have the values we find for them and no explanation of these values will ever be found.

(2) The observed values are necessary to the logic consistency of physics.

(3) The observed values are of non-local origin.

I imagine few will be satisfied with the first of the possibilities. I also imagine most physicists prefer (2). But what if (3) should be correct? Could the curious values we observe for the dimensionless numbers be connected with the particular oscillating and finite region in which we happen to live? If this were so, the universe would be far richer in its possibilities and content than we normally imagine. In other regions the numbers would be different and the gross properties of matter, the science of chemistry for example, would be entirely changed.

A VISIT TO THE LOWER AMAZON

IN the summer of 1964 a visit was made to the lower reaches of the Amazon by a party of four naturalists, namely, I. R. Bishop of the Department of Biology, Guy's Hospital Medical School, who acted as leader of the expedition, E. C. Tatchell of the same department, D. Walliker of the London School of Hygiene and Tropical Medicine and Dr. J. C. Garnham who acted as medical officer.

The party had a number of objectives the most definite being to make collections of parasites of the blood and tissues of various vertebrates, to collect a variety of vertebrate animals and also to attempt to arrange for the return to Great Britain of some living specimens of the South American lungfish, *Lepidosiren*. Other objectives were to introduce the members of the party to various scientists, laboratories and working conditions in Brazil and also to see whether air travel now made it possible for a biologist to go from Britain to Brazil for a comparatively short time, such as a long vacation, and accomplish a worth-while amount of work.

The heavy baggage of the party, including collecting gear and some hydrographic apparatus, was shipped from Britain in May, but the first member of the party to leave was I. R. Bishop, who flew out on June 16; he arrived in Manaus, approximately 1,000 miles up the River Amazon, on June 19, having made a short stop at Belém, where he visited the Goeldi Museum (director, Dr. D. Albuquerque) and the Instituto Evandro Chagas (director, Dr. Orlando Costa) and confirmed arrangements which had been agreed by correspondence that the last three weeks of the trip should be spent at these institutes in Belém (Fig. 1).

On arriving at Manaus, Bishop received a very cordial welcome from Dr. W. Rodrigues, the acting director of the Instituto Nacional de Pesquisas da Amazonia (I.N.P.A.) the director (Dr. Djalma Batista) being on leave. The remaining three members of the party left London on June 30 and arrived in Manaus on July 2.

While the party was in Manaus it was based on the Instituto, Dr. Batista and his staff giving them every possible facility, including living accommodation, laboratory space, and most important the use of a launch, technical assistant and crew to make collecting excursions up and down the river.

The tentative plans laid before leaving London now suffered a minor reverse as the boat carrying the collecting gear, etc., was much delayed and, instead of arriving at Manaus almost at the same time as the main party, was more than a fortnight late and collecting was entirely dependent on facilities provided by others. Fortunately Bishop had soon after his arrival been introduced to Dr. Rudolph Friburgo, who, besides being a keen amateur

Fig. 1. Sketch map of the Lower Amazon showing localities visited

naturalist, is a civil engineer and at that time was in charge of the construction of a road being built through the forest and which had reached a point 130 km north-east of Manaus. At 105 km from Manaus Dr. Friburgo had a temporary home and camp to which he invited the party so that while awaiting their stores they could become acquainted with the forest. A technician was lent by I.N.P.A., and in his company the party spent eleven days collecting birds, mammals and amphibians and acquiring a first-hand knowledge of the forest. The darkness under the leaf canopy was what had been expected, but what came as a surprise were both the undulating nature of the forest floor and the ease with which it was possible to travel through the forest as the undergrowth, except for a few yards on the edge of any clearing where the sun could penetrate, was very thin under the dense leaf canopy and there was also a paucity of animal life. The forest was also extremely silent, the stillness being broken only by the cries of toucans and parrots and the outbursts of howling monkeys the calls of which could be heard over large distances. One member of the party (J. C. G.), who has had experience of the African tropical forest, has remarked that he was particularly impressed by the contrast between the forest in the two continents.

This phase of the work came to an end when the heavy baggage arrived at Manaus and the party returned to see it through the customs, to unpack and to select the equipment required for the next stage which was an excursion up the Rio Negro. As has been mentioned, a launch with crew and sleeping accommodation for all was lent by I.N.P.A. and on July 25 the journey began (Fig. 2).

The rainy season had ended only shortly before the party arrived in Brazil and the water-level was still high; the Rio Negro has low banks and thus the high river floods into the adjacent forest, in some places for distances of several hundred yards. This has the effect of driving from the area all the truly terrestrial animals and there is little in the way of animal life. This applies to man also, and there are few habitations on this river and only in those few places where the land is above flood-level can any settlement be attempted. Attention was mainly confined to the river itself, in which the notorious flesh-eating fish, the *Piranha* (used as food by the crew), is abundant, as are also dolphins, and to the birds—numerous parrots and toucans were seen and occasionally a hawk.

This journey was continued with frequent halts until on the fifth day the confluence of the Rio Negro with the Rio Branco (about 290 km from Manaus) was reached. Here the bank is higher and a suitable place was found to make fast for several days. Collections made here consisted

of fish, lizards and frogs, and hydrological observations were made on a nearby lake. A film record of the swarming behaviour of 'mud puddle clubs' of butterflies was also made. After a stop of five days the return commenced and Manaus was reached on August 3.

Before leaving for Brazil several lines of enquiry had been followed with the view of ascertaining whether it would be possible for the expedition to charter a suitable boat for work in the Manaus region which could then be used for the journey down stream to Belém so that further collections could be made on this journey if opportunity offered. The advice that was received before departure was very conflicting, and, in fact, this course of action proved impossible. Small boats of suitable construction and robustness are all engaged in working for their owners. It was therefore reluctantly decided that the journey to Belém would have to be made by passenger ship. This, however, meant that departure for Belém need not be immediate and the extended use of the I.N.P.A. launch was gratefully accepted and a journey made up the main stream of the Amazon, which here changes its name to the Rio Solimões. This journey took the party to the village of Codajaz (about 250 km from Manaus) (Fig. 2).

The banks of the Rio Solimões were visibly higher than those of the Rio Negro. This had the effect of preventing the seasonal flooding and also allowed for considerable agriculture on the banks themselves. Large areas of the forest along the riverside had been cleared to provide grazing for cattle. Houses, farming communities and townships were frequently passed and it was rare to be out of sight of some habitation whereas on the Rio Negro this had been the rule. From the banks large quantities of floating vegetation extended into the mainstream of the river. At first sight this appeared solid, but as the boat passed, the wash caused the floating vegetation to rise and fall and as the waves passed beneath it the surface of the floating vegetation appeared to ripple as if blown by a strong wind. From time to time portions of these floating mats broke away and became islands drifting downstream, and they appeared to remain intact for many miles. This may be of practical significance in animal transport. Collections made from these floating islands show that mosquito larvae are not infrequent and by this means are transported over long distances, a fact that must be remembered if local mosquito eradication schemes are attempted.

Owing to the fact that Codajaz is frequently visited by research workers from I.N.P.A. the technician, Mozarth, who had been attached to the party, knew several families in the village and enlisted their help in getting together a number of *caçadores* (hunters), and a team of four went off on hunting trips each morning and returned with their catch in the afternoons; it consisted mainly of mammals which were examined for parasites, their skins and skulls being preserved for further examination.

The small boys of the district added various animals to the collection from butterflies to sloths, bats and alligators. These collections were supervised by Walliker and Bishop while Tatchell and Garnham made several trips to various lakes and rivers to study the freshwater biology and hydrology of the region. Dr. Garnham was also able, with help from the officials of the public service (S.E.S.P.), to undertake some clinical helminthological investigations.

The stay at Codajaz was most productive, both of specimens and of scientific information, and it was with some reluctance that on August 18 the return journey to Manaus was begun. Five live specimens of *Iguana*, two more than 3 ft. long, and two Tegu were flown back to London. One *Iguana* died shortly after arrival but the other four were presented to the Zoological Society of London and placed on display in the menagerie. A photograph of one of these specimens appeared in the Society's annual report.

After arriving at Manaus, Walliker and Garnham paid another visit to Dr. Friburgo (at Camp 105 km) while Bishop and Tatchell repacked the equipment for the journey to Belém. This voyage started on August 29, and

Fig. 2. Sketch map of Manaus region showing localities visited. (1) Manaus; (2) camp 105 km from Manaus; (3) mouth of Rio Branco; (4) Codajaz; (5) Itacoatiara.

after a stop of three days at Itacoatiara (about 100 km downstream) to load brazil-nuts, Belém was reached on September 5. Now the party found itself in considerable difficulty as, having come down an international waterway on a British steamer, the chief customs official at Belém held that the party were seeking to re-enter Brazil and questioned the validity of the documents presented. The equipment was impounded and only after a fortnight was the position clarified and the equipment released on September 19, and after a few days it had to be repacked for the journey home. During the stay at Belém the party was almost entirely dependent on borrowed equipment, and it is a pleasure to record that the party was made extremely welcome by Dr. Orlando Costa of the Evandro Chagas Institute, who provided laboratory facilities, and by Dr. Daley Albuquerque of the Goeldi Museum, who provided more laboratory facilities and excellent living accommodation in the zoological garden attached to the Museum. If it had not been for the kindness of these two directors no scientific work would have been possible during the time spent separated from the equipment.

Here Walliker had the assistance of the Belém Virus Laboratory in taking blood smears from animals in the Utinga Forest. Garnham turned to the problem of chloroquine-resistant malaria, which had been reported to be present in the area and, with the aid of Dr. Lins of the Evandro Chagas Institute, visited the hospitals and made valuable contacts with physicians dealing with malaria infection. Whether drug-resistant malaria is present or not is a matter of debate among the experts in Brazil, and the matter remains unresolved.

Throughout the visit to Amazonia constant enquiry had been made concerning the possibility of obtaining specimens of the South American lungfish, and in the Manaus region the answers to such enquiries were always that it could be found but not in this precise locality or

season. At Belém hopes were higher, for it is well known that it occurs in the island of Marajó which is close by. Eventually a local fisherman was persuaded to try to attempt to find some in one of the many waterways which run through the outlying parts of Belém. These are shallow ditches which are kept full of water by the influence of the tides in the delta; these ditches contain much vegetation (see Fig. 3) and are used by the local inhabitants as places in which to dispose of household refuse and rubbish of all kinds and the water is turbid, of unpleasant odour and, as shown by the electronic recording gear, of negligible oxygen content. At night the fisherman stretched a net across such a ditch and then by working it along the stream and beating the rooted vegetation drove fish into the net. In one night's fishing fifteen specimens of *Lepidosiren* were taken of which twelve were flown back to London in suitable containers. Six were sent independently and six accompanied the members of the expedition on the return journey and all arrived in good condition.

Thus the objective of obtaining living lungfish was attained. What of the other objectives? It is now, at the time of writing, some ten months since the party returned. During this time work on the material has proceeded and a preliminary scientific report was made at a meeting of the Linnean Society of London on February 18. A series of reports on the parasitological materials, some of which on protozoa are in the press, is being prepared by Walliker, and in a joint report on some aspects of filariasis he is being joined by Garnham. Bishop and Tatchell will make their own reports in due course; Bishop has also been responsible for sending material to experts on various aspects of the work, largely systematic, for their detailed investigation. In addition, a colour 16-mm film recording the expedition and its work is nearing completion. Work on the lungfish is proceeding in the Biology Department at

Fig. 3. The habitat of *Lepidosiren* in Belém, Pará, Brazil

Luoy's Hospital Medical School under the guidance of Prof. G. E. H. Foxon.

Of the more indefinite objectives, that of getting to know and working in conjunction with Brazilian scientists has most certainly been achieved. All the members of the party are grateful for the splendid assistance and co-operation received at every turn, not only from those who have been named here, but also from all those whom they met both professionally and socially who helped to make their visit so pleasant; in particular, mention should be made of the British vice-consuls at Manaus and Belém.

In conclusion, the members of the party and all concerned with the expedition thank the many individuals, commercial companies and public bodies who by their financial support and other aid enabled this journey to be undertaken. Among the public bodies the following should be especially mentioned: the Zoological Society of London, the Medical Research Council and particularly the Wellcome Trust, which by a generous guarantee made the project possible.

I. R. BISHOP
G. E. H. FOXON

NUTRITION AND ITS INTERNATIONAL RECOGNITION

By SIR RUDOLPH A. PETERS, F.R.S.

THIS subject has a very long history, but in spite of this the International Union of Nutritional Sciences is not yet accepted as one of the 'international unions' of the International Council of Scientific Unions—even at a time when we all know that a proper knowledge of nutrition is more than ever necessary to save the increasing population of the world from famine. A haphazard use of food does not matter so much when there is plenty, because the body can adapt itself to a badly balanced diet to some extent. It is, however, now vital to know how to use our food with the greatest economy. Many years ago, for example, Chittenden and his colleagues (Chittenden, R. H., *Physiological Economy in Nutrition*, New York, 1904) showed that protein requirements of adults could be much reduced without damage to health.

Why, then, is there delay in accepting nutritional science as a separate science? Probably part of the reason is the complexity of the subject. It involves physics, chemistry, physiology, biochemistry, pharmacology, pathology and medicine, and extends to sociology especially in regard to food habits and the preparation of foodstuffs. Each of these sciences sees only a small part of a complexity. Fifty years ago, nutrition seemed almost synonymous with biochemistry and Gowland Hopkins shared a Nobel Prize with Eijkmann for his part in delineating vitamins, and for showing so clearly that nutrition was a qualitative subject and not just a matter of energetics, the so-called isocaloric value of foodstuffs. This was followed by an outburst of activity in isolating and synthesizing various vitamin factors, in the furtherance of which the U.K. Medical Research Council played a considerable part. For the past eighteen years, however, those concerned with granting finance for research have turned to 'pastures new', witness: The isolation of enzymes, the unravelling of protein structure and the excitement of the nucleic acids and genetics. The result is that at the present time few research workers have been trained in the rigorous and lengthy discipline of nutritional research—which is emphatically not just 'the feeding of a

few rats'. From many points of view, even from that of space travel, we want to know much more about the interaction of the various compounds making up a diet.

The problems extend, of course, beyond man into the animal kingdom. In agriculture, for example, there is the problem of digestion in the ruminant. The micro-organisms in the rumen, bacteria and protozoa, by a controlled fermentation set up a digestion of substances such as cellulose, which the secreted enzymes of the digestive tract cannot digest; and so they turn inedible substances into food for man. Anatomy, physiology, biochemistry and microbiology are all involved in this work; but none of these sciences, as such, is interested in the implications of ruminant digestion for the utilization of the world's grassland to feed its populations.

Again, it is the business of the soil scientist, who may be geographer, physicist and chemist, to show that certain strata of the world's surface lack particular elements, such as copper or cobalt; and the biochemist will relate this to plant growth and to enzymes present. It is the business of the nutritionist to relate these discoveries to the health of the grazing animal, and so ultimately to the food supply of populations. Actually, it has often been investigated in reverse, starting with the ill-health of the animal on the natural vegetation.

It is to be noted that the International Union of Nutritional Sciences has been in existence since 1948; and it has at present the support of seventeen national members of the International Council of Scientific Unions. At intervals of three years, it has held six successful international congresses; the last one was in Edinburgh under the presidency of Sir David Cuthbertson. There will always be a need for close relations with organizations such as the Food and Agriculture Organization, the World Health Organization and Unesco; but this very necessity makes it all the more important for nutrition to have a firm scientific basis within the organization of the International Council of Scientific Unions.

NEWS and VIEWS

Science Research Council Support for University Science and Technology

THE Science Research Council has set up a new University Science and Technology Board under the chairmanship of Sir Ewart Jones, Waynflete professor of organic chemistry in the University of Oxford, to advise on the support which the Council should give to science and technology in the universities. The new Board will advise the Council on the award of grants for the support of university research, as well as studentships and fellow-

ships for the training of young postgraduate scientists: support for university scientific research and advanced training will thus be closely integrated. The scope of the Board will include science and technology; it will therefore work in close touch with the other Research Councils and the Ministry of Technology. The Council has already set up a Nuclear Physics Board under the chairmanship of Prof. C. F. Powell, and an Astronomy, Space and Radio Board under the chairmanship of Sir Bernard Lovell. Part of the support previously given to university research and training by the Department of Scientific and Industrial

Research, namely that concerned with earth sciences and ecology, has been taken over by the Natural Environment Research Council; and most of the support given in the past by the Department of Scientific and Industrial Research to university research and training in some parts of the human sciences (particularly sociology and psychology applied in industry) will be taken over by the new Social Science Research Council which is being set up by the Government following the recommendation of the Heyworth Committee.

The new Board replaces the Research Grants Committee and the Postgraduate Training Awards Committee of the Department of Scientific and Industrial Research. The membership of the Board is as follows: *Chairman*, Sir Ewart Jones. *Members*, Prof. B. Bleaney, Dr. Lee's professor of physics, University of Oxford; Prof. R. Brown, Regius professor of botany, University of Edinburgh; Dr. A. Caress, Imperial Chemical Industries, Ltd.; Prof. G. C. Drew, professor of psychology, University College, London; Dr. H. M. Finnis, International Research and Development Co., Ltd.; Prof. H. Ford, professor of applied mechanics, Imperial College of Science and Technology; Prof. M. R. Gavin, professor of electronic engineering, University College of North Wales, Bangor; Lord Halsbury; Dr. J. W. Menter, Tube Investments Ltd.; Prof. R. S. Nyholm, professor of chemistry, University College, London; Prof. G. Porter, Firth professor of chemistry, University of Sheffield; Prof. E. J. Richards, professor of applied acoustics, director of Institute of Sound and Vibration Research, University of Southampton; Prof. A. L. Roberts, Livesey professor of fuel technology, University of Leeds; Dr. J. E. Smith, secretary of the Marine Biological Association of the United Kingdom and director of the Laboratory; Prof. I. N. Sneddon, Simson professor of mathematics, University of Glasgow; Sir Peter Venables, vice-chancellor, University of Aston in Birmingham. *Assessors*, University Grants Committee and the Ministry of Technology.

Directorate of Overseas Surveys :

Mr. G. J. Humphries, C.M.G., O.B.E.

MR. G. J. HUMPHRIES retires this month as director of Overseas Surveys of the Ministry of Overseas Development, and Surveys adviser to the Minister. Mr. Humphries was born in 1900, and after three years at the University of Reading joined the Colonial Survey service in Nigeria in 1928. He was with the Royal Engineer Survey from 1939 until 1946, attaining the rank of lieutenant-colonel. From 1944 he was responsible (under Brigadier Hotine, director of Military Surveys) for the planning and organization of what was originally known as the Directorate of Colonial Surveys. Mr. Humphries was deputy director of this from its start at Bushy Park in 1946 with responsibility for the field side of the work. He was appointed director in 1963 on the retirement of Brigadier Hotine. When the tellurometer was being perfected in South Africa in 1957 he played a major part in its acceptance by geodesists and land surveyors by his advocacy and by organizing the completion by tellurometer in one month of a 400-mile precise traverse in Kenya which would have taken two years or more by conventional methods—the first major field task for which this revolutionary survey instrument was used. In addition to his control of the field side of the Directorate with parties working all over the Commonwealth, Mr. Humphries was responsible for the technical side of the selection and training of British surveyors for the Colonial Survey departments and of the training of African and other overseas surveyors in Britain. His experience and judgment of character have played an important part in the growth of these departments and in their effective evolution after the independence of the countries concerned. Mr. Humphries was awarded an O.B.E. in 1954 and a C.M.G. in 1965.

Mr. W. D. C. Wiggins, O.B.E.

MR. W. D. C. WIGGINS has been appointed to succeed Mr. Humphries as director of Overseas Surveys and Surveys adviser. Born in 1905, Mr. Wiggins was a scholar of King's School, Canterbury, and went to University College, London. He joined the Nigerian Survey Department in 1928 and served in the Royal Engineers from 1939 until 1946, attaining the rank of lieutenant-colonel. He was appointed assistant director to the Directorate on its formation in 1946 and deputy director in 1948 with responsibility mainly for the mapping side at Tolworth. He was awarded an O.B.E. in 1957.

Standards Division, National Physical Laboratory, Teddington :
Dr. H. Barrell, C.B.E.

DR. H. BARRELL, who will be retiring from his post of superintendent of the Standards Division of the National Physical Laboratory at the end of March 1966, joined the Metrology Division, as it then was, in 1923. He took his degree in physics at the Royal College of Science, where as a demonstrator he later worked with A. Fowler on ultra-violet spectroscopy in the early years of quantum theory. Dr. Barrell's own experimental work has been largely devoted to precise measurements of wave-lengths in the visible spectrum and their applications to the measurements of length. An outstanding contribution, made jointly with Mr. J. E. Sears during 1932–38, was the determination of the metre and the yard in wave-lengths of light and of the refractive index and dispersion of air. From 1939 until 1945 he was responsible for mechanical gauging of ammunition to which he applied pneumatic methods, so initiating an important development in the work of the Division. Dr. Barrell was appointed superintendent of the Metrology Division in 1953 in succession to Dr. F. H. Rolt. In 1958, in a re-organization of the National Physical Laboratory, the Metrology Division was combined with other groups to form the Standards Division. Dr. Barrell has been particularly concerned with the decision, taken in 1960, to define the metre in terms of the wave-length of an orange line in the spectrum of krypton-86: he has directed the Division's contribution to the international co-operative programme of research organized by the International Committee for Weights and Measures and he is a member of that Committee's Advisory Committee for the Definition of the Metre. In 1954, following the death of Mr. J. E. Sears, he was elected to the International Committee. He was a member of the British delegations to the General Conferences of Weights and Measures of 1948, 1954, 1960 and 1964. As chairman of the international Advisory Committee for the Definition of the Second, Dr. Barrell has been influential in securing agreement on the definition of time in terms of an atomic frequency, a decision which, like that on the metre, depends heavily on the experimental work of his own Division. Dr. Barrell's superintendency has been a time of rapid change. From a small group concerned mainly with measurements in classical physics and engineering, the Division has grown to be the largest in the Laboratory with responsibility for the fundamental units, for the most precise measurements of length, mass, time and frequency, electrical quantities and temperature, and for much of the routine test work of the Laboratory as well. This growth Dr. Barrell has taken in his stride while maintaining and encouraging the many research activities and manifold international responsibilities of the Division. He retires at a time when the international repute of the Division is high in the field, a true reflexion of the imaginative guidance he has given. He was awarded a C.B.E. in 1962.

Dr. A. H. Cook

DR. BARRELL is being succeeded next April by Dr. A. H. Cook, who was educated at Westcliff High School and Corpus Christi College, Cambridge. After graduating

in physics in 1943, Dr. Cook worked at the Admiralty Signal Establishment on electrical measurements at micro-wave frequencies and returned to Cambridge in 1946 to specialize in the Department of Geodesy and Geophysics on pendulum and gravity meter surveys of the gravitational field in Britain and continental Europe. He joined the staff of the National Physical Laboratory in 1952 and has gained international renown for his outstandingly accurate determinations of fundamental quantities, in particular the density of mercury, wave-lengths of light and gravitational acceleration at Teddington, which are of basic importance in the establishment of more precise standards of measurement. During recent years his interests have extended to metrological applications of gas lasers and to the development of advanced methods and equipment for interferometric spectroscopy in the extreme ultra-violet region. He is planning, in association with the University of Trieste, a new determination of the gravitational constant, using for the experiment a torsion pendulum 80 m long suspended in a large cave near Trieste. Dr. Cook is a member of the British National Committees for Geodesy and Geophysics and for Space Research and holds official positions in the International Union of Geodesy and Geophysics and the International Astronomical Union. He has served on the Council of the Royal Astronomical Society and is joint editor of the *Geophysical Journal*. He is now being granted sabbatical leave until he takes up his new appointment and will be a Visiting Fellow at the Joint Institute for Laboratory Astrophysics at Boulder, Colorado, which is directed by the University of Colorado and the American National Bureau of Standards.

U.S. National Bureau of Standards :

Dr. W. J. Youden

DR. WILLIAM J. YOUSEN has retired from the Applied Mathematics Division at the National Bureau of Standards. Dr. Youden, who had been with the Bureau since 1948, was responsible for significant research in mathematical statistics, especially in the field of experiment design, and vigorously promoted sound understanding and increased utilization of modern statistical techniques throughout science and industry. His most outstanding achievements are in the field of combinatorial arrangements for the conduct of scientific experiments. One class of these designs, constructed for use when test conditions vary from one group of tests to another, is known as the Youden Square. He has also contributed methods for interlaboratory tests that are used in biological and medical applications as well as in the physical sciences. Before joining the Bureau staff, Dr. Youden carried out scientific and statistical research at the Boyce Thompson Institute for Plant Research, Inc. He was an instructor at the University of Rochester, and has had temporary professional appointments at Columbia University, the University of North Carolina, and the University of Chicago. Born in Australia, Dr. Youden received a B.S. in chemistry, mathematics, and engineering from the University of Rochester in 1921 and an M.A. and Ph.D. from Columbia University in 1924 in chemistry. Dr. Youden plans in the future to take up a teaching position in the College of Engineering at the George Washington University.

Dr. P. H. Verdier

DR. PETER H. VERDIER recently joined the staff of the Molecular Properties Section, Polymers Division, of the Institute for Materials Research of the National Bureau of Standards as a physical chemist. He will undertake research of the dynamics of polymer chains by means of the Monte Carlo system, and will specialize in the effects of excluded volume interactions on the motion of polymer chains. Dr. Verdier joined the Bureau from the Union Carbide Research Institute where he was engaged in

research on molecular structure and dynamics. Born in 1931 in Pasadena, California, Dr. Verdier received his B.S., with honours, in chemistry from the California Institute of Technology in 1952. In 1957 he received his Ph.D. in physical chemistry from Harvard University. He was a Research Associate in chemistry at the Massachusetts Institute of Technology during 1957-58, and a Research Fellow at Harvard during 1958-59.

Chemistry at Battersea College of Technology :

Prof. J. A. Elvidge

DR. J. A. ELVIDGE has been appointed to the second chair in the Department of Chemistry at Battersea College of Technology, the proposed University of Surrey. Educated at Habercashers' Aske's Hampstead School (now at Elstree) and the Imperial College of Science and Technology, he graduated with honours in 1943 and gained the Hofmann Prize. As a William Gilles and then Beit Fellow, he carried out research on penicillin in a team under Sir Ian Heilbron and Dr. A. H. Cook, which gained him a London Ph.D. in 1946. Appointed lecturer at the (then) Royal Technical College, Glasgow, in 1947, he worked with Prof. F. S. Spring on gliotoxin and aspergillus acid. On returning to the Imperial College of Science and Technology in 1949, he collaborated with (then) Prof. R. P. Linstead in research on unsaturated acids and lactones, and macrocyclic compounds and intermediates, and took charge of the newly instituted third-year course for specialists in organic chemistry, which remained his major and expanding teaching interest. He was promoted to senior lecturer in 1956 and to a University readership in organic chemistry in 1962, and at this time received a London D.Sc. Dr. Elvidge's research interests include heterocyclic syntheses from malonyl chloride, reactions of nitrogen heterocycles, tetrazaporphins, metal derivatives, and applications of proton magnetic resonance to structural problems and in the determination of aromaticity. He has collaborated with chemists at the Brewing Industry Research Foundation on the structure and enolization of acylcyclopentanone products from hop resin. He is a consultant to Fisons Pest Control, Ltd., and prizes close relations with Imperial Chemical Industries Dyestuffs Division. He has been a lecturer and tutor at the recent summer schools on nuclear magnetic resonance spectroscopy organized by the Royal Institute of Chemistry. In his new post, Dr. Elvidge looks forward to introducing nuclear magnetic resonance techniques to an established research school, to further contacts with industry, and participation in the arrangements for the proposed new University at Guildford.

1965 Guggenheim International Astronautics Award :

Prof. M. V. Keldysh

THE Daniel and Florence Guggenheim International Astronautics Award for 1965 has been conferred on Prof. Mstislav V. Keldysh, of the U.S.S.R. Academy of Sciences in Moscow. Prof. Keldysh has made valuable contributions to the progress of astronautics and he is well known for his extensive research in problems of aerodynamics, fluid mechanics, rocket propulsion, and vibration theory. For several years he has been directing work on rocket propulsion and the mechanics of space flight. Prof. Keldysh has been president of the U.S.S.R. Academy of Sciences since 1961 and is also a member of the Praesidium of that Academy's Committee on Theoretical and Applied Mechanics and of the editorial boards of several scientific journals. He has received numerous awards in recognition of his achievements. He is a Corresponding Member of the Engineering Sciences Section of the International Academy of Astronautics. The Guggenheim International Astronautics Award, which is offered by the International Academy of Astronautics, carries with it a prize of 1,000 dollars.

U.K. Atomic Energy Authority and Central Electricity Generating Board Co-operation Scheme

To facilitate the close co-operation which already exists between the United Kingdom Atomic Energy Authority and the Central Electricity Generating Board, it has been decided that there should be cross-membership between the two bodies. Mr. F. Cousins, Minister of Technology, has accordingly appointed Mr. E. S. Booth, the engineering member of the Central Electricity Generating Board, to be a part-time member of the Atomic Energy Authority, and Mr. F. Lee, Minister of Power, has appointed Mr. J. C. C. Stewart, the Member for Reactors of the Atomic Energy Authority, to be a part-time member of the Central Electricity Generating Board.

Professional and Technical Staff in the Civil Service

IN a recent issue of *State Service*, the journal of the Institution of Professional Civil Servants (August 1965), the general secretary, M. W. McCall, commenting on the 1964 report of the Civil Service Commission, stresses the continuous failure to recruit sufficient professional and technical staff. Candidates could only be recommended for about a third of basic grade vacancies for engineers, although two-thirds of the vacancies at main grade and higher levels were filled. Similarly, while two-thirds of the vacancies for architects in these grades were filled, only one-sixth of those at the basic grade were filled. Only 85 out of 220 vacancies for mechanical and electrical engineers were filled and only 327 out of 546 vacancies in the technical classes. The Board of Inland Revenue is stated to be short of a fifth of its complement of professional valuers, the work of the Patent Office is delayed for a like reason, and the shortage of Factory Inspectors has been reflected for years in the low frequency of inspections. To remedy this situation, Mr. McCall urges that pay and careers must be offered to scientists, technologists and technicians which indicate that they are no longer regarded as inferior or second- and third-rate. Their training and talents should be used to the field in terms of the work they are qualified to do and they should have full opportunity of promotion to the highest posts.

Aid to Education Overseas

THE Overseas Development Institute has issued the report of a Ditchley Foundation Conference held at Ditchley Park during March 26-29, 1965 (*Aid to Education: An Anglo-American Appraisal*. Report of a Ditchley Foundation Conference held at Ditchley Park, March 26-29, 1965. Rapporteur: Peter Williams. Pp. 52. London: The Overseas Development Institute, in association with The Ditchley Foundation, 1965. 3s. 6d.). Dealing with educational aid, especially in Africa, Asia, and the Caribbean, it considers first the donor programmes and policies of educational aid, and second the requirements of the recipient countries. Next it sets forth some conclusions about priorities and the principles of educational aid before making specific suggestions for future Anglo-American co-operation in this field. Recognizing the need for a balance between education and the economy, the Conference gave much thought to the determination of priorities between types and levels of education. It also emphasized that educational aid is a two-way process and that the developing countries should not copy too rigidly the institutions and techniques of developed countries. It is emphasized that the developing countries will need educational assistance for a very long time ahead. The Conference strongly urged that Britain and the United States should, as the major donor countries, prepare themselves to meet the challenge by establishing permanent resource centres on which to draw in their aid programmes.

It suggests that it would be wise to establish small cadres of experts on a permanent footing and to create

supernumerary posts in Government departments, universities and other institutions. Moreover, appropriate arrangements should be made for training the personnel involved, so that specialists could be seconded for overseas assignments as required. In this way a permanent supply of experts would be ensured. The advantages of involving non-government institutions are also emphasized, as well as the need for a strategy of educational aid. It is suggested that existing forms of co-operation, like the Teachers for East Africa Scheme and programmes of joint support for overseas universities, should be extended and supplemented by new schemes. Specific areas for future co-operation should include the development of curricula and text-books, the teaching of English (application of modern techniques (like educational television and programme learning), educational research, the training of teachers, experiments in comprehensive secondary school education and work on methods of reducing the costs of education. Pilot projects and experiments should be financed so far as possible by aid donors. Direct linking of American, British and overseas teacher training institutes for various purposes is recommended as well as co-ordination of British and American programmes for teacher refresher courses in developing countries.

Water Affairs in Zambia

THE independence of Zambia came about in 1964 and inevitably brought with it great changes in the administration and conduct of the work of official organizations concerned with development of natural resources, including water. The Department of Water Affairs had to adjust itself to the new conditions, and how it set about this task is revealed in the recently published annual report of the Department of Water Affairs for the year 1964 (Pp. 9. Lusaka: Government Printer, 1965. 2s.). One of the major difficulties which had to be faced was the loss to the Water Department of many well-trained and experienced members of the professional and technical staff who decided to leave the country and seek a new life elsewhere. The report devotes considerable attention, and rightly so, to the serious staff position thus created. Notwithstanding this handicap, and the rather alarming number of vacancies existing in the various grades of water engineers and technical staff, actually 39 at the close of 1964, the amount of development work accomplished in many areas now under regional planning, including investigation and construction of new water works, appears quite remarkable. Special mention is made of the work of the Hydrological Branch in respect of the Kafue Basin Survey, where an investigation of the river system was considerably extended by installation of many new stations chiefly in the area between Mumbwa and the Copperbelt. Good progress was also made in rehabilitation of old drainage canals and also in construction of new canals in Barotseland. It is recorded that there has since been a notable improvement in drainage of areas affected by these works; crops can now be grown where formerly the land was far too wet. Further sections of the report summarize the present position of the Copperbelt water supply; other work of the Hydrological Branch; water projects in view; water communications and drainage in the Bangweulu Swamps; drainage and communications in Barotseland; the functions of the Water Board and of the Geological and Drilling Sections.

Scientific Research in the Development of Polish Industry

IN the *Review of the Polish Academy of Sciences* for January-March 1965, I. Malecki describes the role of scientific research in the development of Polish industry since the Second World War. The period 1945-52 was

largely one of reconstruction. During 1953-57 the technical base was expanded, and this period was marked by an extension of the industrial institutes, which in 1957 numbered 79, employing 22,600 scientific and technical workers, compared with 1,000 in the research institutes of the Polish Academy of Sciences. The next period, 1958-63, was notable for modernization and a general raising of the level of production, and has since been followed by one of systematization and development of the work of the research centres. Throughout these phases, Dr. Malecki emphasizes the attention given to the exploitation of natural resources and to the creation of the technical infra-structure; to improving the properties and production of novel technical materials; to the design of buildings and of major technological processes; and to the development of electronics and machine production. The situation of the medical sciences in Poland is described by K. Rowinski in a further article in the same issue. The physiological sciences are still inadequately developed in Poland, but the pharmacological and pharmaceutical sciences have contributed considerably to the supply of drugs. In biochemistry developments have been more in fundamental research than in the clinical field. Valuable work has been done in histology and in medical microbiology, and the clinical sciences are stated to be progressing favourably.

The Pharmaceutical Industry

In recent years the pharmaceutical industry in Britain, and, for that matter, overseas also, has been the target for much adverse criticism on several counts, notably high prices of some new drugs, inadequate clinical testing of newly marketed products, the problem of 'side effects', and a belief that profits in the industry overall are excessive and nationally unwarranted. That much of this criticism is ill-informed and unjustified is made clear in two recent publications which are worthy of a much wider circulation than they will probably achieve. The first is *Astra Annual Report 1964* (Pp. 40. Södertälje: Astra, 1965). This is in English and, in the course of his annual review, the President of the Astra Group says: "During the year there was a continued trend in most countries toward more rigorous legislation for pharmaceutical products. Behind this is the urgent desire to improve safety conditions for the consumer. However, the divergent regulations in various countries and the growing bureaucratic interference create great difficulties for the industry and delay the introduction of new drugs, yet have failed to ensure a corresponding degree of safety. Efforts are being made to produce more unified rules governing new drug registration". A much more detailed exposition of the problems of the industry to-day appears in a recent issue of *CIBA Journal* which, in a series of impressive articles lavishly illustrated, is devoted to the subject (33. Pp. 62. CIBA Ltd., Basle, Switzerland; Spring 1965). This is again in English and the titles of the articles are self-explanatory. The editorial foreword discusses at some length "The Intricate Mechanism of Drug Discovery, Manufacturing, and Control". R. Larose (CIBA Dorval) details something of "The Canadian Pharmaceutical Industry at Work". "The Viability of the British Pharmaceutical Industry" is ably revealed by A. W. Morrison (CIBA Horsham). An anonymous article entitled "Working in the Light: The New Drug Research Unit at Horsham" describes the modern building there now at the disposal of those engaged in the search for new and better pharmaceuticals (*Nature*, 207, 236; 1965). Prof. H. Bloch (CIBA Basle) writes on "The High and Rising Importance of Biology in Pharma Research". Dr. Matthys Staehelin (CIBA Basle) contributes an account of "Biochemistry—Cornerstone of Biological Research". It is impossible to read these articles without coming to the conclusion that, in spite of sins of omission and commission such as there may have been in the past, the international outlook of the industry

to-day is to work for the betterment of mankind and to spare neither energy nor money in giving the medical profession the tools it needs to alleviate human suffering. One gets the impression that Government interference in what is after all pure scientific research, if carried to excess, must inevitably defeat its own object. Freedom to explore, to formulate, to think ahead, untrammelled by obstructive regulations, is the privilege of every qualified worker in fundamental scientific research; in no case is this freedom more vital to the community than in the practice of pharmacology.

Load-bearing Brickwork

At a meeting of the Building Materials Section of the British Ceramic Society held at the Building Centre, Store Street, London, during November 18-19, 1964, nine papers were presented dealing with some fundamental properties of structural brickwork. These have now been published under the collective title *Load-Bearing Brickwork* (*Proc. Brit. Ceramic Soc.*, No. 4. (July 1965): *Load-Bearing Brickwork*. Pp. 121. Stoke-on-Trent: British Ceramic Society. 25s.). The first paper, by D. Lenzner, is on "Design of Creep Machines for Brickwork" and deals with the creep characteristics of brickwork and particularly the various creep machines designed for testing brick piers, walls and brick mortar. Next, M. E. C. Stedham contributes results of his further work to establish crushing tests of 9-in. brickwork cubes as an indication of the strength of brickwork built of the same materials, under the title of "Quality Control for Load-Bearing Brickwork". The third paper entitled "Measurement of Strains in Load-Bearing Brickwork", by R. N. Picken and A. W. Hendry, describes the construction, mode of use, and application of the vibrating-wire strain-gauge to the measurement of strains in the brickwork at the base of a brick chimney during dismantling at Hem Heath Colliery, Stoke-on-Trent. J. M. Plowman in "The Modulus of Elasticity of Brickwork" compares the elastic moduli obtained from brickwork made from bricks and mortar of wide ranges of strength. "Comparative Tests on $\frac{1}{4}$ - and $\frac{1}{2}$ -scale Model Brickwork Piers and Walls", by A. W. Hendry and C. K. Murthy, describes their investigations carried out to ascertain the suitability of model bricks; tests that had been carried out on full-size brick piers at the Building Research Station and on full-size walls at the Department of Building Science, University of Liverpool, were repeated on $\frac{1}{4}$ - and $\frac{1}{2}$ -scale models; their results show that, for given strengths of brick and mortar, subject to certain provisos, the strength of full-size brickwork can be reproduced with reasonable accuracy by means of model tests. The sixth paper by S. Prasan, A. W. Hendry and F. E. Bradshaw, entitled "Crushing Tests on Storey-height Walls 4.5 in. Thick", discusses the results of tests on seventeen walls 4.5 in. thick loaded between reinforced concrete slabs and their significance in terms of the various mechanical factors involved. A paper by L. G. Simms on "The Strength of Walls built in the Laboratory with some Types of Clay Bricks and Blocks" briefly describes loading-tests on walls of storey-height built in the laboratory (Building Research Station) with clay bricks and blocks. F. H. Clews discusses "Experiments to Assess the Durability of Bricks and Brickwork": an account of natural exposure tests, with examples of techniques applied by other workers, and of the methods used at the Mellor-Grøn Laboratories on fifty-nine batches of bricks and thirty-two batches of roofing tiles. Finally, a paper entitled "The Design and Economics of High Load-Bearing Brick Structures", by R. A. Sefton-Jenkins, dealing with the design of highly stressed brickwork, includes comparison of various codes of practice with the British, discussion of economics of load-bearing brickwork compared with other structural forms, and a plea for more research in this subject as a basis of a new British Code of Practice.

Thermal Comfort in Industry

In everyday circumstances of industrial and, for that matter, domestic life, the range of temperature and humidity that can be tolerated by the human body is really quite small. Human reaction to different thermal conditions, especially in factories and offices, is a subject of research falling within the ever-widening scope of ergonomics. In this context, there has recently been published a booklet by Dr. R. H. Fox, of the Division of Human Physiology, Medical Research Council (Ministry of Technology). *Ergonomics for Industry*, No. 8: *Thermal Comfort in Industry*. Pp. 52. London: H.M.S.O. Obtainable from Warren Spring Laboratory, Stevenage, Herts. 1965. *Gratis*. The essential theme of this guide-book (for that is the underlying purpose of each issue in the *Ergonomics for Industry* series so far available) is not only a discussion of human reactions to environmental conditions of temperature and humidity, but also the ways and means of ensuring that optimum conditions may be established. Quoting one specific instance (well illustrated), the author says: "Few people would choose to live in a greenhouse all the year round, yet the indoor climate in this modern office building is not very different". Thus attention is directed to the different conditions that different types of work require. It is recommended that buildings should be planned with the comfort and working efficiency of the occupants in mind. It stresses the problems encountered in some modern office buildings where large areas of glass prevail, with relatively little, if any, provision for air conditioning; such conditions result in overheating and consequent fatigue in summer, and coldness and discomfort in winter. Either of these extremes is inimical in the long run to welfare and efficiency. It is admitted that in some cases extremes of temperature occur and thermal control is impracticable; in the event, protective clothing and training are necessary; the principles involved in insulating individuals in such environments are outlined. The illustrations in this booklet are impressive, so is the advice and practical guidance throughout the text. Suggestions are made for further reading on this important subject of human and environmental relationship, while sources of specialist advice, and information on general ergonomic questions and on heating, ventilation and insulation of buildings, conclude a most practical exposition of the problems involved.

Science Information and Documentation Services

A *World Guide to Science Information and Documentation Services*, issued by Unesco, is intended primarily as a guide to the location of such services dealing with the natural sciences (Pp. 211. Paris: Unesco, 1965. 9 francs; 13s.; 2.50 dollars). Technology is to be dealt with in a separate volume, but services for agriculture and medicine are expressly included because of their paramount importance for the developing countries. The *Guide*, which is in both French and English, is based on 403 completed forms returned in a detailed questionnaire, and covers 144 institutions representing 85 countries. The institutions are listed under countries in alphabetical order of their titles and the entries indicate the subjects covered, approximate holdings and services offered. There is also an alphabetical list of institutions and a subject index. It might be noted that there are only three entries for the United Kingdom: Aslib; the National Lending Library for Science and Technology; and the Science Museum Library.

British Art, 1740-70

THE American Philosophical Society has rendered a notable service to art-history by publishing Prof. E. K. Waterhouse's Jayne Lectures for 1964 under the title *Three Decades of British Art, 1740-70 (Memoirs of the*

American Philosophical Society, 63. Pp. xii+77. Philadelphia: American Philosophical Society, 1965. 2 dollars). But these discourses can be interpreted more widely than that, namely, as a conspectus of what a certain cross-section of society was like at that period. In general, we note the advent of Italian influence, culminating in the Grand Style, and with it the works of such masters as Hogarth, Reynolds and Gainsborough. To men of science, there are several points of interest, but two stand out clearly. One is the statue of Handel by Roubiliac (illustrated), so complex and rather voluptuous, when one recalls that it is by the same hand as the ascetic and sublime "Newton" in Trinity College Chapel. How versatile and sympathetic the sculptor must have been to respond like that in his portrayal of two utterly different characters. The second matter is the 'character' (by Reynolds) of Raphael's *School of Athens*. This is indeed an odd fantasy—the great Greek philosophers and mathematicians replaced by eighteenth-century milords and their fellow-travellers, seen against a background of Gothic niches (in place of Raphael's classical statues). Sir Joshua was far too great a man to perpetrate this merely for fun. He was showing up his contemporaries, and incidentally instructing himself quite effectively. Altogether a most intriguing episode, described with exceptional insight.

University of Leicester, Department of Museum Studies

WITH the assistance of a £15,000 grant from the Gulbankian Foundation, the University of Leicester has established a postgraduate Department of Museum Studies. The University has appointed H. R. Singleton, at present director of the City Museum, Sheffield, to be the first director of this new Department. His duties will commence on January 1, 1966, and it is expected that the first students will be admitted in the following October. Initially, the intake will be confined to graduates with qualifications in archaeology or geology, but in subsequent years it is hoped to accept graduates from other disciplines. The one-year, full-time course for a Certificate in Museum Studies will be designed to offer intending entrants to the museum profession a preliminary training in museum administration and organization, in the museum application of their particular subject, and in the practical side of museum work.

National Museums of Southern Rhodesia

THE report of the Trustees and Directors of the National Museums of Southern Rhodesia for the year ended December 31, 1964, records the probably unique event of the opening of three new museum buildings within one year, namely, the National Museum, Bulawayo, the Queen Victoria Museum, Salisbury, and the Umtali Museum (Pp. 25. Salisbury: National Museums of Southern Rhodesia, 1965). With the future in mind, each of the buildings is designed to allow for expansion, and the sites have sufficient ground reserved for extension. Although the fittings in the exhibition galleries were far advanced for the opening ceremonies, much still remains to be done. This great development has come at a time when political considerations in Africa have disturbed the progress which took place in the immediate post-war years. As a result, funds are not so freely available as formerly, and so, with Government sanction, it was decided to levy an entrance charge to help to offset the greatly increased maintenance costs on buildings some two-and-a-half times the size of the old. In view of the educational nature of the organization, school parties are admitted free.

Meat from Wild Animals in Africa

In the past decade increased attention has been directed towards the management and potential utilization of wild

imals in Africa as a natural resource in order to assist filling the world's larder. The more scientific investigation work which has been carried out in this field has been brought together by the Commonwealth Agricultural Bureaux in a recent publication, issued as *Technical Communication* No. 16, entitled *The Meat Production Potential of Wild Animals in Africa—A Review of Biological Knowledge* (By Lee M. Talbot, W. J. A. Payne, H. P. Ledger, Norma D. Verdcourt and Martha H. Talbot. Pp. vii+42. Barnham Royal, Bucks.: Commonwealth Agricultural Bureaux, 1965. 13s. 6d.). This directs attention to the possibilities of exploiting some of the game animals in under-developed countries. The review points out that the African continent contains the greatest diversity of indigenous large mammals to be found anywhere in the world. The wild ungulates considered range from the 10-lb. dik-dik to the 5-ton African elephant. The determination of the numbers of animals present in an area has represented a major problem. In general, the most accurate estimations were made from light aircraft, and the results agreed closely with those obtained by Royal Air Force photo-reconnaissance planes. Some animals were marked so that they could be recognized later and their movements and growth-rates followed. Agriculturists and meat technologists will be interested in the figures given under the heading "Carcase Composition". Killing-out percentages quoted include the following: East African zebu steers, 40 to more than 60; wildebeest, 50; topi and xongoni, 53; and impala and gazelle, both about 60. In general, the amount of fat is consistently low, so that the carcase yield is relatively constant within a given species.

Soil Catena

SINCE Milne used the word 'catena' as a mapping unit in East Africa, some thirty years ago, to describe a sequence of soils, extending from hill top to valley bottom, which is repeated across the contours of the landscape, it has been interpreted in various ways in different countries. Such matters as parent material, erosion, intensity of leaching and mobility of sesquioxides have tended to complicate the original concept, which was intended to apply to one climatic zone, a medium-rainfall area of the tropics, and to differences in level. It is most useful, therefore, to have a documented statement on the subject by J. P. Watson in *Soils and Fertilizers* (28, No. 4, 307; 1965). The same number contains a review by Dan H. Yaalon of a Russian book on *Soil Geographical Zoning* of the U.S.S.R., and a description by W. E. Calton of a soil-map of Africa (scale 1 : 5,000,000) with an explanatory monograph by J. L. d'Hooze. The former is a systematic inventory of the natural soil and climatic resources of the U.S.S.R.; the latter is a large inventory of the soils of Africa with seven sheets of soil maps.

Soil Survey of Great Britain

THE work completed and in progress during 1964, under the auspices of the Soil Survey Research Board of the Agricultural Research Council, is described in its seventeenth report (Pp. v+46. London: Agricultural Research Council. Obtainable from H.M.S.O. 1965. 6s. net). Publications include a memoir on "The Soils and Land Use of the District around Aylesbury and Hemel Hempstead", two bulletins on the soils of the Middle Teign Valley and of six counties in the West Midlands, and a soil map of 432 square miles (sheet 57) around Forfar. Two more memoirs on the Mendip District and on the country around Haddington and Eyemouth, and eleven sheets of soil maps, are in the press. Members of staff of the Soil Survey also contributed 21 papers to scientific journals and conferences. This report contains short accounts of the nature of the soils found in various parts of Britain, with emphasis on unusual features, and some classifications of soil series. There is also a summary of

the laboratory investigations that have been carried out. The Soil Survey is frequently called on to make special surveys, and the assistance rendered to such authorities as the Forestry Commission, the Nature Conservancy, the Agricultural Advisory Services, and planning and archaeological departments is briefly recorded. There are also two maps showing the areas in which field work has been completed or is in progress.

Pituitary Transplants in the Teleost

J. N. BALL and his colleagues have taken very effective advantage of the development of a technique for hypophysectomizing the viviparous teleost *Poecilia (Mollinnesia) formosa*, and for establishing homografts of the pituitary (*Phil. Trans. Roy. Soc., B: Functional Capacity of Ectopic Pituitary Transplants in the Teleost Poecilia formosa, Comparative Discussion on the Transplanted Pituitary*. By J. N. Ball, Madeleine Oliverreau, Anna M. Slicher, and K. D. Kallman. Pp. 69-99+plates 18-21. London: The Royal Society, 1964. 18s.; 2.70 dollars). The ectopic gland survives, but without the direct link with the hypothalamus on which its relationships with the central nervous system normally depend. It has thus become possible to analyse with some precision the degree to which the various ad-nohypophysial functions are influenced by signals from the central nervous system. In some respects the results are similar to those that have been reported from studies of the ectopic pituitary in mammals. Abundant prolactin is secreted by the ectopic graft, but there is a marked reduction or elimination of the secretion of growth hormone and gonadotrophins. But the teleosts have pursued their own independent line of evolution, and it is not surprising, therefore, to find some interesting points of difference in their hypothalamo-adenohypophysial relationships. Corticotrophin secretion seems to be less dependent on hypothalamic stimulation than it is in mammals and in this respect there is some resemblance between *Poecilia* and amphibians. More unexpected is the finding that the ectopic adenohypophysis of the fish secretes thyrotrophic hormone at a higher rate than normal. This means that in the intact animal the hypothalamus must be exerting an inhibitory influence on this function, whereas in mammals, as is well known, the influence is excitatory. The situation in amphibians in this respect is somewhat obscure, although there is certainly some evidence for an excitatory influence. The authors conclude that at present *Poecilia* seems to be peculiar in the way in which its thyrotrophin secretion is regulated.

New Zealand Geochemical Group

At the University of Otago on August 18, 1965, during the annual conference of the New Zealand Institute of Chemistry, a meeting attended by twenty-one interested persons unanimously approved a motion by Prof. D. S. Coombs, seconded by Mr. A. H. Horn, to form a New Zealand Geochemical Group. Officers elected were Dr. J. Rogers, chairman, Mr. S. H. Wilson, secretary, and Dr. A. Ewart, with power to co-opt. This motion crystallized a recommendation from a meeting chaired by Dr. A. J. Ellis at Lower Hutt during the centenary of the New Zealand Geological Survey. The New Zealand Geochemical Group plans to promote discussion and co-operation in geochemical problems between scientists of different disciplines and backgrounds by a newsletter and symposia at conferences. Liaison is also proposed with geochemical societies overseas. It is hoped to arrange a meeting of the Group during the international symposium on "Volcanology" in New Zealand between November 21 and December 3, which a considerable number of geochemists from overseas will be attending. Anyone interested in the Group is invited to register with Mr. S. H. Wilson, Institute of Nuclear Sciences, Private Bag, Lower Hutt.

Bryozoan Research

SIXTEEN zoologists and palaeontologists from nine countries were participants in the first international conference on "Post-Palaeozoic Bryozoa" held at the University of Stockholm, Sweden, during May 24-31, 1965, with Ivar Hesseland and the Geological Institute as hosts. To assure continuation of frequent and informal exchange of information, ideas, and techniques, the conference established the International Bryozoology Association, membership in which is open to all workers engaged in research on Bryozoa, Palaeozoic as well as post-Palaeozoic. Plans are being made for a second conference in 1968. The Stockholm conference included four days of informal discussion (led by A. H. Cheetham) of morphology, systematics, biometrics, ecology-palaeoecology, and stratigraphy of post-Palaeozoic Bryozoa and four days of collecting (led by Sten Schager and Ole Berthelsen) of Bryozoa from Senonian-Danian deposits in southern Sweden (Scania) and eastern Denmark (Zealand). Further information about the International Bryozoology Association or the *Proceedings* of the Stockholm conference can be obtained from A. H. Cheetham, Geological Institute, Kungstensgatan 45, Stockholm Va.; or from P. L. Cook, Department of Zoology, British Museum (Natural History), London, S.W.7.

The Official University of the Congo at Elisabethville

THE July 1965 issue of Publications of the Official University of the Congo at Elisabethville contains an "Introduction to the Study of Economic Development: General Theories" by A. Cecchella, who describes representative theories of the evolution of economic thought on problems of development (*Publications de l'Université Officielle du Congo à Elisabethville*, 8. *Introduction à l'Étude du Développement Économique les Théories Générales*, by Aldo Cecchella. Pp. 158. Elisabethville: Université Officielle du Congo à Elisabethville, 1965). There are four chapters. The first deals with economic development in the classic thought of J. B. Say, D. Ricardo and R. Malthus, and the second with the Marxist analysis of economic development. The third is directed to the work of J. Schumpeter and the fourth to the Keynesian analysis of modern theories of economic development.

Announcements

DR. F. M. LEVER has been appointed manager of the Research Laboratories of Johnson, Matthey and Co., Ltd. He succeeds Dr. J. C. Chaston, who has retired from the Company. For the past eighteen years Dr. Lever has been head of Chemical and Extraction Metallurgy Research in the Laboratories.

MR. P. M. J. WOODHEAD, senior scientific officer at the Fisheries Laboratories of the Ministry of Agriculture, Fisheries and Food, Lowestoft, has been appointed to the position of scientific and administrative officer at the Heron Island Research Station of the Great Barrier Reef Committee in Queensland, by the University of Queensland.

THE second edition of the "Biographical Index of Members, Correspondents and Associates of the Royal Academy of Belgium" covers the years 1769-1963, correcting and completing the first edition published in 1948 (*Index Biographique des Membres, Correspondants et Associés de l'Académie Royale de Belgique de 1769 à 1963*. Pp. 299. Bruxelles: Académie Royale des Sciences, des Lettres et des Beaux-Arts de Belgique, 1964). The entries indicate the field of work of the member; for deceased members, reference is given to obituary notices or other tributes.

THE *Annals of the Library Association, 1877 to 1960*, edited on behalf of the Library History Group by W. A.

Munford, is a chronological record of the main even affecting the work of the Association since its foundation in 1877 (Pp. 128. London: The Library Association, 1965. 22s.; L.A. members, 16s. 6d.). Mainly of interest to librarians, it includes dates of publication of certain reports, books or pamphlets which may be of wider utility.

A SYMPOSIUM on "Cellular Plastics", the next in the series of Borough Polytechnic symposia on "Plastics and Polymer Technology", will be held at the Borough Polytechnic during November 4-5. Further information can be obtained from the Secretary, Borough Polytechnic Borough Road, London, S.E.1.

A CELEBRATION conference, to mark the 200th anniversary of the founding of the Freiberg Mining Academy in East Germany, will be held at the Academy during November 9-14. Further information can be obtained from Mardie Henry, Lex Hornsby and Partners, Ltd. Wellington House, 125 Strand, London, W.C.2.

A ONE-DAY conference on "Access to Information", to discuss the implications of a national bibliographical centre and any other ideas which might improve access to information, will be held in the Beveridge Hall, Senate House, University of London, on October 26. Further information can be obtained from the Research Officer Library Association, Malet Place, London, W.C.1.

A MEETING of the Photobiology Group will be held at the Chester Beatty Research Institute, London, on October 27. The programme will include a paper and conversation on monochromators for photobiology. Further information can be obtained from Dr. J. D. Moreland, Institute of Ophthalmology, Judd Street, London, W.C.1.

THE eighteenth annual conference and exhibit on "Engineering in Medicine and Biology", sponsored by the Institute of Electronic and Electrical Engineers and the Instrument Society of America, with participation of the American Society of Mechanical Engineers, will be held in Philadelphia during November 10-12. Further information can be obtained from Dr. H. P. Schwan, University of Pennsylvania, Philadelphia, Pennsylvania.

THE third international conference on "Hyperbaric Medicine", sponsored jointly by the Duke University Medical Center and the Committee on Hyperbaric Oxygenation of the National Academy of Sciences—National Research Council, will be held in Durham, North Carolina, during November 17-20. Further information can be obtained from the Secretariat, Box 2928, Duke University Medical Center, Durham, North Carolina.

THE annual Pittsburgh Diffraction Conference will be held at the Mellon Institute, Pittsburgh, during November 3-5. The programme will include (1) special sessions on metals, ceramics, structures, crystal physics (lattice dynamics and crystalline imperfections) and instrumentation and techniques, and (2) a symposium on "Texture and Preferred Orientation in Polymers". Further information can be obtained from Paul A. Flinn, Carnegie Institute of Technology, Pittsburgh, Pennsylvania 15213.

ERRATUM. In the communication entitled "Response of Time-dependent Materials to Oscillatory Motion" by Dr. J. Harris, which was published on p. 744 of the August 14, 1965, issue of *Nature*, equation (5) should read as follows:

$$M(t - t') = \int_0^{\infty} \frac{R(\Pi)}{\Pi} \exp - \left(\frac{t - t'}{\Pi} \right) d\Pi \quad (5)$$

SPECTROSCOPY IN AUSTRALIA

THE fifth Australian Spectroscopy Conference, sponsored by the Spectroscopy Committee of the Australian Academy of Science and organized by a Committee under the chairmanship of Dr. A. R. H. Cole, was held at Perth, at the University of Western Australia, during May 31–June 2.

The Conference was opened by Dr. A. L. G. Rees, who welcomed those attending of whom fourteen were from overseas. The programme consisted of morning and afternoon sessions on each of the three days, usually with concurrent lectures on topics in different sections of spectroscopy. The sections were infra-red and Raman spectroscopy; visible, ultra-violet and theoretical spectroscopy; nuclear and electron spin resonance spectroscopy; atomic absorption spectroscopy; mass spectroscopy and X-ray fluorescence and electron absorption spectroscopy. More than eighty-five papers were presented, of which nine were review papers by invited speakers.

The section on infra-red and Raman spectroscopy opened with a review paper given by Prof. N. S. Sheppard (University of East Anglia) on infra-red band shapes and rotational motion in condensed phases. It was shown that simple molecules such as methyl chloride undergo at least hindered rotation in solution while molecules adsorbed on to surfaces may rotate about the bond linking the molecule to the surface.

The first of the succeeding papers of this section was a report by A. D. E. Pullin (Monash University) on the operation of a commercially made interferometer designed to measure infra-red spectra down to 20 cm^{-1} . A brief outline of the theory of operation and the factors determining spectral range and resolution was given. Examples of spectra obtained were shown.

Several succeeding papers discussed the use of infra-red and Raman spectra to assign particular molecules to their correct point group or to indicate preferred conformations of flexible molecules. J. F. Horwood (C.S.I.R.O., Division of Dairy Research, Melbourne) and J. K. Wilmschurst (C.S.I.R.O., Division of Chemical Physics, Melbourne) suggested that dimethyl oxalate in the liquid and vapour phases was non-planar with point group symmetry C_2 . E. Spinner (Australian National University) reported Raman polarization data for aqueous solutions of formates and pointed out that these were consistent with C_2 rather than C_{2v} symmetry for the formate ion. N. S. Ham (C.S.I.R.O., Division of Chemical Physics, Melbourne) discussed the spectra of thionyl aniline, C_6H_5NSO , and showed that it was consistent with a *cis* planar CNSO structure though the *trans* structure could not be eliminated. R. A. Cummins (Defence Standards Laboratories, Melbourne) discussed the preferred conformations present in alkyl tin compounds of the type R_nSnCl_{4-n} , and H. Lee and J. K. Wilmschurst (C.S.I.R.O., Division of Chemical Physics, Melbourne) the conformations of trimethyl orthoformate and tetramethyl orthocarbonate. The vibrational data are consistent with an unsymmetrical *trans-gauche-gauche* arrangement of the methyl carbons with respect to the formate hydrogen in trimethyl orthoformate and with a distorted S_4 structure for the tetramethyl carbonate.

In a second paper concerned with the infra-red spectra of several acetates (hydroxyanthraquinone acetate, phenyl acetate, α and β naphthyl acetates) these authors attribute the observed doubling of the carbonyl stretching absorption to Fermi resonance with combination tones. A. R. H. Cole and L. M. Engelhardt (University of Western Australia) analysed the rotational fine structure of several bands of acrolein in terms of an approximate symmetric top and showed that the data are consistent with the existence of only the *trans* form. Analyses of vibration-rotation bands of methylphosphine and isotopic deriva-

tives, which are also approximate symmetric tops, leading to values of $\frac{1}{2}(B + C)$ in agreement with microwave data were reported by A. G. Moritz (Defence Standards Laboratories, Melbourne). In a later paper A. G. Moritz discussed the vibrational assignment of CH_3SCN and related molecules. G. C. Barraclough and M. Sinclair (University of Melbourne) discussed the vibrational assignment of dicarbonyldinitrosyl iron, and D. E. Clegg (University of Queensland) that of $(CH_3)_3Pt(NH_3)_2^+$ ($(CH_3)_3Pt(NH_3)_2Cl$ in water and deuterium oxide). M. S. Farrell and T. L. Whateley (A.A.E.C. Research Establishment, Lucas Heights) reported the infra-red spectra of beryllium nitrate complexes with organic-phosphorus compounds such as tri-*n*-butyl phosphate, tri-*n*-octyl phosphine oxide and di-(2-ethylhexyl)-phosphoric acid. B. H. James and P. E. Rogasch (Weapons Research Establishment, Adelaide) discussed the changes of the in-plane bending frequencies of substituted phenols with respect to electronic effects and hydrogen bond formation, and R. H. Laby (Department of Agriculture, Melbourne) and T. C. Morton (School of Biochemistry, University of Melbourne) discussed inter- and intra-molecular hydrogen bonding in hydroxy- and nitro-hydroxy-coumarins.

Three papers on the use of infra-red spectroscopy in adsorption studies were presented: M. Clark, B. A. Morrow, N. Sheppard and J. W. Ward (University of Cambridge and the University of East Anglia) discussed the infra-red spectra obtained from the examination of the systems olefine-silica supported nickel (or supported platinum)-hydrogen; N. W. Cant and L. H. Little (University of Western Australia) the spectra for ammonia and deuterio ammonia adsorbed on silica; and W. I. Stuart and T. L. Whateley (A.A.E.C. Research Establishment, Lucas Heights, N.S.W.) the spectra of carbon monoxide, of carbon dioxide, and of water on magnesium oxide and on beryllium oxide. Below 200°C carbon dioxide is chemisorbed on beryllium oxide, to form a carbonate and also a singly charged anion, probably CO_2^- . Above 300°C only the carbonate is formed.

Several infra-red investigations of compounds of biological interest were described. A. J. Michell described polarized infra-red studies of some monosaccharides, related to cellulose and xylan, which were chosen because their crystal structures had been investigated and because they were more easily crystallizable than higher members of the sugar series. E. G. Bendit (C.S.I.R.O., Division of Textile Physics, Sydney) discussed the changes of the infra-red spectra of α - and β -keratin of horse-tail hair on hydration and deuteration. Deuteration tests on α -keratin showed that helical peptide NH groups begin to deuterate immediately, while non-helical peptide NH groups continue to exchange throughout the process. R. D. B. Fraser and E. Suzuk (C.S.I.R.O., Division of Protein Chemistry, Melbourne) considered the roles of inter- and intra-molecular hydrogen bonds in modifying the characteristic vibrations of polypeptides. In an interesting paper R. H. Laby (Department of Agriculture, Melbourne) discussed the infra-red spectra of glycine, glycyglycine and β -alanine in aqueous salt solutions and related spectral changes to conformational changes brought out by differing salt solutions.

Two interesting papers in this section were contributed by visiting Indian scientists. Prof. R. S. Krishnan (Indian Institute of Science, Bangalore) gave an account of the theory of Raman spectra of cubic diatomic crystals; and Prof. C. N. R. Rao (Indian Institute of Technology, Kanpur), in a paper on charge transfer and hydrogen-bonded complexes of π -donors, surveyed correlations of spectroscopic and thermodynamic data with substituent effects and other structural parameters. Also concerned with complexes of the charge-transfer type was a paper by

N. F. Cheetham and A. D. E. Pullin (Monash University), who described an infra-red study of molecular complexes between perfluoroalkyl bromides (and iodides) or perfluoroaryl bromides (or iodides) and tertiary amines. The stoichiometry of the complexes had been previously determined by phase studies.

Of wide interest was a paper by G. R. Hunt and J. W. Salisbury (Lunar and Planetary Research Station, Bedford, Massachusetts) on the infra-red techniques used in an attempt to gain information about the silicates present in selected areas of the Moon's surface. These techniques were based on selective reflexion of the radiation by silicates of the various chemical types that might be present on the Moon's surface. A standard spectrometer, suitably modified, was used in conjunction with 42-in. and 69-in. reflecting telescopes.

Many of the papers presented in section B, that on visible, ultra-violet and theoretical spectroscopy, reflected the present-day strong interest in problems peculiar to transitions in condensed phases on one hand, and on the other to the new problems that obtrude when the spectra of larger molecules are examined in the vapour phase by high resolution methods.

Prof. D. P. Craig (University College, London), in an invited paper, reviewed the recent advances in the theory of molecular excitons. Prof. Craig described first the modifications of the theory of crystal spectra consequent on taking into account the finite time of propagation of electrical fields in solids, and then discussed, among other topics, how application of theory to crystal spectra could give information on long-range interactions between molecules. Prof. Craig ended his lecture by showing how information about the degree of order in melts could be obtained from their electronic spectra, taking azulene as his example. In a subsequent paper R. G. Body (University of Sydney) gave the results of a mathematical investigation, based on the principles of coupled oscillators, of the positions and polarization of absorptions in crystals due to impurities. Approximate formulae derived enabled the normalized second moment of the energy-level distribution in the pure crystal to be deduced from the spectra of isotopic impurities. Under certain conditions non isotopic impurities can display striking intensity anomalies. The theme of solid-state spectra was also the subject of papers by G. W. Robinson (California Institute of Technology) on exciton structure in benzene, who gave experimental data on the exciton splitting in the benzene ${}^1B_{2u}$ electronic state and in a number of vibrational levels in the ground electronic state, and by M. Chowdhury, D. McClure and E. Zalewski (University of Chicago), who described an investigation of the Zeeman effect on the singlet triplet spectrum of pyrazine. Single crystals at $\sim 4^\circ \text{K}$ and pulsed magnetic fields up to 200,000 gauss were used. Two bands, believed to be two Davydov components, at 26,254 and 26,261 cm^{-1} were assigned, from their polarization and Zeeman effect characteristics, to an electric dipole transition along the N—N axis and to a magnetic dipole transition respectively. Later in the Conference, in an invited address, Prof. McClure described the way in which spectroscopic states of various ions are split when they are subjected to crystal fields of cubic lower symmetry. He illustrated this for various transition elements and rare earth ions, and showed how some complex crystal spectra yielded to this form of analysis. B. N. Figgis and L. G. B. Wadley presented preliminary polarization data on a charge transfer band at about 24,000 cm^{-1} in dilute solid solutions of potassium ferrioxalate in potassium cobalt cyanide. Several papers concerned with solvent effects on electronic bands were presented. N. S. Bayliss and G. Wills-Johnson (University of Western Australia) examined the effect of solvents on the intensities of electronic bands of molecules in solution by perturbation methods, deriving the perturbation from the solvent reaction field. The shortcomings of, and possible improvements to, this approach were outlined.

The predictions of the theory were compared with experimental results for the $n \rightarrow \pi^*$ transitions in aliphatic ketones and nitroparaffins in solution. D. W. Jamieson (University of Queensland) and C. R. Boston and G. M. Smith (Oak Ridge National Laboratory, U.S.A.) described the effects of change of temperature and change of cation species on the weak band at $\sim 195 \text{ m}\mu$ and the strong band at $\sim 300 \text{ m}\mu$ in molten nitrates in terms of coulombic interactions, variations in environmental symmetry and variation in vibrational energy.

The third invited speaker was Dr. D. A. Ramsay (National Research Council, Ottawa). Dr. Ramsay began his address by pointing out that in general, in electronic spectra, doppler motion broadens lines sufficiently to limit useful resolution to one in half a million, a natural limit attained by the best present-day spectrographs. For larger molecules, the lines of which are closer than this the observed band contour can be compared with contour computed from overlapping line intensities. (Later in the conference the application of this procedure to part of the azulene spectrum was described by A. J. McHugh of the University of Sydney.) Dr. Ramsay then turned his attention to spectra of smaller molecules recently obtained at the Ottawa laboratories. The structures of glyoxal in the ground and excited states were being deduced from its spectra. Preliminary estimates of bond-lengths for the first excited singlet state were in agreement with predictions of molecular orbital theory for conjugated molecules of this type (glyoxal, butadiene, etc.). After reference to recently obtained spectra of the allyl and glyoxal radicals, Dr. Ramsay described techniques being developed at the Ottawa laboratories to aid the analysis of spectra. The 'J sorting' technique was based on the injection of microwave power to disturb the rotational levels of one of the combining states. This technique was limited to molecules having a microwave spectrum. In a later paper with Prof. A. D. Buckingham (University of Bristol), Dr. Ramsay described experiments carried out at the Ottawa laboratories on the use of Stark modulation to help identify the type of transitions. An alternating voltage was applied to the plates of a Stark cell at 400 c/s and the Stark-modulated spectrum recorded at high resolution with the photomultiplier detector connected to a lock-in amplifier tuned to 800 c/s so that only lines with appreciable Stark effect were recorded. Up to 80 kV was applied across the 3-cm width of the 2-m long cell. A relatively high pressure ($\sim 300 \text{ cm}$) of SF_6 was introduced in the cell to prevent electrical breakdown. For a symmetric top the Stark splittings are dependent on $\mu^2 K M / J(J+1)$ so that Stark modulation favours the selection of lines of higher K and lower J values. By use of polarized light the Q lines can be identified as those more prominent in parallel polarization and those more prominent in perpendicular polarization as P and R lines. As well as helping to assign lines as P , Q or R , dipole moments of molecules in excited states could be obtained from Stark splittings.

In the field of vapour phase aromatic spectra G. C. Morris (University of Melbourne) presented results on band positions, oscillator strengths and assigned transitions for the region 20,000–54,000 cm^{-1} of the absorption spectra of naphthalene. J. P. Byrne and I. G. Ross (University of Sydney) considered the cause of spectral diffuseness: not all diffuseness is due to predissociation; plain congestion of the spectrum can be a cause in larger molecules. L. M. Logan and I. G. Ross (University of Sydney), in a paper concerning molecular fluorescence in the vapour state, considered the interaction between the original excited vapour state and the vibronic states of the lower electronic levels. R. H. Kennet (Weapons Research Establishment, Adelaide) described a method for the determination of the intensity distribution in an unresolved molecular band, and described features of the profile that are dependent only on temperature and from which the temperature may be deduced.

In an interesting paper C. E. Kendall (National Biological Standards Laboratory, Canberra) attempted to delineate more closely the possible connexion between the carcinogenic activity of molecules and their electron donor characteristics by using experimental data and energies of the highest occupied molecular orbitals of the donors to prepare a common index of donor activity for comparison with charge transfer data. When this comparison is made—for example, in the form of a plot—complexes of early all carcinogens lie in a fairly narrow range, especially when the common acceptor is chloranil. Possibly some type of electron transfer may be involved in a cell, with an electron acceptor of similar affinity to chloranil. K. Selinger (School of General Studies, Canberra) in a paper on excimer formation described an investigation of the effect of pressure on the kinetics of formation of excited dimers by molecules in the excited state. Where the activation energy of dimer formation is low, the increase in viscosity with pressure does not affect the process and the decrease in volume accompanying excited dimer formation can be measured.

The diversity of uses of spectroscopic techniques was exemplified by a paper by K. J. Taylor and P. D. Jarman (University of Western Australia) on an aspect of sonoluminescent spectra. When cavities in liquids, produced ultrasonically, collapse, thermally excited radiation is emitted. If the liquid contains a dissolved alkali metal salt, the alkali lines appear in emission displaced and much broadened by interactions with the cavity contents. From these data the relative density of the cavity contents at the time of light emission can be calculated.

Instrumental aspects of spectroscopy were represented by several papers. Dr. S. E. Williams (University of Western Australia), in a review of the development of spectroscopy in the spectral range 1000–20 Å, described the many experimental problems encountered and showed examples of spectra in this region. Dr. Williams emphasized the importance of isoelectronic sequences in the interpretation of such spectra. S. C. Baker (University of Newcastle) described an Ebert-type scanning spectrometer with a resolving power of 500,000 in the tenth order green, and K. J. Taylor and P. D. Jarman described an auto-spectrophotometer for a low-intensity source. The prism can be rotated in either direction in steps by a motor driven by electric pulses derived from a logic circuit which also addresses the integrated output pulses from the photomultiplier into a 400-channel analyser. The memory of the analyser can then be read out as desired.

In a paper on the electronic emission spectrum of the diatomic molecule IF, R. A. Durie (C.S.I.R.O., Division of Coal Research, Sydney) summarized the analysis of the $A'E \rightarrow X_{\pi}^2$ transition and the derived molecular constants. C. Candler (Bendigo Technical College, Bendigo) presented a paper on the mechanism of dye sensitization of photographic emulsions.

Two other invited review papers related to electronic spectroscopy were given during the conference. Dr. Wilse Robinson (California Institute of Technology) gave a stimulating account of photosynthesis from a spectroscopist's point of view, stressing the essentials and the two-quantum process involved; and Prof. R. D. Brown (Monash University) outlined the best methods now available for calculating the energies of excited states of molecules. Introduction of configuration interaction led to a large number of integrals. Their number could be reduced by the approximation of zero differential overlap. Improved energies could be obtained by semi-empirical corrections to decrease nearest neighbour repulsion integrals to allow for the effects of electron correlation. Prof. Brown ended his address by showing how the calculated energies of the electronic states of benzene varied according to which of the up-to-date methods of correcting these integrals was adopted.

Two papers in this section formed a close link with those in the mass spectroscopy section. J. D. Morrison

(C.S.I.R.O., Division of Chemical Physics, Melbourne) discussed the application of extended Hückel type calculations on simple molecules to determine if possible the location from which an electron will be ionized and, if the resultant ion dissociated, the most probable fragments and their structures, and A. J. C. Nicholson (C.S.I.R.O., Division of Chemical Physics, Melbourne) reported an investigation of photo-ionization efficiency curves. Ionization potentials of methane, ethane and propane, claimed to be closer to the adiabatic values than those extant, were reported, and it was shown how, from a comparison of photo-ionization efficiency curves, it is possible to identify vibrational and excited states of specific molecular ions.

Section C, dealing with nuclear and electron spin resonance spectroscopy, covered a fairly wide range of interests despite the small number of papers presented.

The analysis of high-resolution nuclear magnetic resonance spectra was considered in a paper by S. N. Stuart (C.S.I.R.O., Division of Chemical Physics, Melbourne), who showed how it was possible to systematize the use of quantum mechanical trace relations in such analyses and illustrated some of the simplifications thus arising.

In the field of proton resonance spectroscopy, the paper by P. J. Black, R. D. Ewens and M. L. Heffernan (Monash University) showed how it was possible, after appropriate corrections had been applied, to correlate proton shifts with molecular orbital electron densities of aromatic heterocycles. R. G. Hillis (Defence Standards Laboratories, Victoria) and N. S. Ham (C.S.I.R.O., Division of Chemical Physics, Melbourne), in studies on a number of methyl-sulphur compounds, used the relation between proton chemical shifts and $^{13}\text{C-H}$ coupling constants to estimate the anisotropy effects present in these substances. The effectiveness of natural abundance ^{13}C -nuclear magnetic resonance spectroscopy as a tool for the analysis of coal derivatives was well illustrated in the paper by R. A. Friedel and H. L. Retcofsky (Bureau of Mines, Pittsburgh Coal Research Centre).

Broad line NMR was well represented by three papers. C. K. Coogan (C.S.I.R.O., Division of Chemical Physics, Melbourne) discussed the investigation of charge distributions in the ionic crystals LiOH and NaSH and showed how a number of other crystal properties could be investigated with NMR. A similar investigation of ionic crystal with a linear triatomic anion was reported by I. D. Campbell (C.S.I.R.O. Division of Chemical Physics, Melbourne). G. J. Jenks (Defence Standards Laboratories, Melbourne) demonstrated the use of tin and nitrogen resonances in the assignment of a structure to tri-*n*-butyltin thiocyanate and reported the presence of an ^{119}Sn - ^{15}N coupling constant.

Electron spin resonance spectroscopy was represented by one paper. K. Kenny (Washington University, St. Louis, U.S.A.) indicated how the use of multi-channel analyses has facilitated the detection of transient free radicals. The application of the technique to living aquarium plants was described.

The section on atomic absorption revealed exciting developments in all aspects of the field. In his invited contribution, A. Walsby (C.S.I.R.O., Division of Chemical Physics, Melbourne) described the successful development by him and his colleagues of several new systems for enhancing and isolating resonance radiation. These include a hollow cathode lamp having a subsidiary discharge that selectively intensified resonance lines 100-fold without increasing line width, and resonance monochromators that can be used both with conventional and high-intensity lamps and that offer the possibility of simultaneous determination of a number of elements. A. Hell (Beckman Instruments, U.S.A.) discussed the optical and mechanical factors involved in obtaining optimum performance from a laminar flow burner and described means of extending analytical range by the use of an infra-red heated spray chamber and solvent conden-

sation system. The addition of 12 elements to those previously determinable in aqueous solution and a general alleviation of chemical interference by the use of high-temperature flames employing O_2-N_2 mixtures and N_2O with acetylene was revealed by J. B. Willis (C.S.I.R.O., Division of Chemical Physics, Melbourne) in a joint paper with M. D. Amos (Techtron, Victoria). In another paper, J. B. Willis stated that examination of atomizer design has resulted in considerable improvement in performance being achieved by precision in construction and by providing means of accurately positioning the capillary. J. V. Sullivan (C.S.I.R.O., Division of Chemical Physics, Melbourne) discussed the construction and performance of high-intensity lamps. The increase in the intensity of the resonance lines has been achieved by exciting the metal atoms, produced by a hollow-cathode discharge with a secondary discharge electrically isolated from the former. He then described a high-intensity lamp which incorporates an additional hollow cathode which selectively modulates the resonance lines and permits the use of low-resolution monochromators for the isolation of resonance lines in complex spectra. W. Slavin (Perkin-Elmer, U.S.A.), in tracing the development of burners, described a design having multiple slots for producing an $N_2O-C_2H_2$ flame of high temperature and stability by the operation of sheathing flames on each side. Examination of the performance of this burner has shown that good agreement with other methods is obtained, that a number of transitions from excited states absorb and that phosphate enhances vanadium absorption. Mrs. J. A. Bowman (C.S.I.R.O., Division of Chemical Physics, Melbourne), in collaboration with J. C. Heerdt (Commonwealth Railways, Port Augusta, South Australia) and J. B. Willis, reported that good agreement could be obtained between atomic absorption measurement on oil dissolved in 2-methyl-4-pentanone and both atomic absorption and colorimetric results on dissolved ash for Cu, Cr, Fe, Pb and Ag, but it was agreed in discussion that the greatest hazard in diagnosis of engine breakdown lies in the sampling of the oil. N. J. Marshall (Bureau of Mineral Resources, Canberra) reported success in the extraction of various substituted thiocarbamate complexes of Cu, Pb, Ni, Co and Te into amyl acetate for the determination of these elements, at parts-per-hundred-million levels, in rocks by atomic absorption; and D. C. Bowditch, jointly with J. A. Powell (both of the Australian Mineral Development Laboratories, Adelaide), that atomic absorption could compete favourably with other means of analysis in the determination of Cu, Zn, Co, Ni, Cd, Mn, Sb, Ag and Bi both at low concentration in geochemical and mill tailing samples and at high concentration in mill feed and product control. After outlining his methods of soil and plant analysis for some 25 major and minor elements by means of flame emission, porous cup spark emission, rotating disk spark emission on a direct reader and chemical concentration followed by cathode layer arc emission (improved by image converter scanning of plates), R. L. Mitchell (Macaulay Institute for Soil Research, Scotland) described, in an invited address, an atomic absorption method for the determination of extractable cobalt at deficiency-levels in soils, stating that considerable gain in sensitivity had recently been achieved by use of a special atomizing system, tuned a.c. amplifier and recorder read-out.

A successful mass spectrometry section was a late addition to the Conference programme. Seven papers were presented; six of these, including an introductory lecture by J. S. Shannon (C.S.I.R.O., Division of Coal Research, Sydney), dealt with structural applications in organic, metal-organic and co-ordination chemistry, and the seventh with an electric quadrupole mass spectrometer (D. Swinger, C.S.I.R.O., Division of Chemical Physics, Melbourne). The structural applications reported included a structural assignment for the complex fungal metabolite sporidesmin C, a tentative structure for the cell growth factor 'Zeatin', a characteristic reaction of 2,6-diaryl oxazole systems in which CO and HCN is eliminated (W. D. Crow, J. Hodgkin, R. Hodges, D. Letham and J. S. Shannon), structures for the Schiff Base bisbenzoylacetone-ethylenediamine and its metal chelates, and the mass spectra of Ph_3M ($M = N, P, As, Sb, Bi$) and related compounds (J. S. Shannon) and of macrorungia alkaloids (R. R. Arndt, K. Biemann, A. Jordaan, V. P. Joynt and J. L. Occolowicz (C.S.I.R.O., Division of Chemical Physics, Melbourne). N. Wasada and I. Tsuchiya (Government Chemical Industrial Research Institute, Tokyo), E. Yoshii (Faculty of Pharmaceutical Sciences, University of Toyama, Japan), T. Fukuzumi (Japan Monopoly Corporation) and E. Watanabe (Japan Electron Optics Laboratory) reported on fragmentation patterns and discussed their mechanisms for santonins and their derivatives and also for solanone, an unsaturated branched aliphatic ketone from tobacco leaf. J. L. Occolowicz (Defence Research Laboratories, Melbourne) and J. M. Swan (C.S.I.R.O., Division of Organic Chemistry, Melbourne) described the mass spectra of phosphonic esters $RPO(OR')$, and dichlorides $RPOCl_2$, and emphasized the value of keeping an accurate electron balance in the formulation of ionic equations. General patterns for the decomposition of odd electron (radical) ions and even electron ions were described. In a stimulating discussion of these papers the approach of the organic chemists to the interpretation of mass spectra was criticized as lacking quantitative energy factors; in reply it was maintained that, provided the approach was utilized correctly, there was at present no better method available.

The remaining section of the Conference consisted of four papers on X-ray spectroscopy. D. McKenzie (Australian Iron and Steel, Wollongong, N.S.W.) described the analysis of coals by X-ray spectroscopy, and in a paper by K. Norrish (C.S.I.R.O., Division of Soils, Adelaide) a technique for silicate analysis was described in which the sample was fused with lithium borate glass, with added lanthanum oxide and cast in a penny-shaped disk. Advantages of this technique include durability of sample and uniform background. K. Norrish and C. G. Gurr (C.S.I.R.O., Division of Soils, Adelaide) described an automatic pulse-height analyser for use in X-ray spectrography, and J. B. Swann (University of Western Australia) the energy of electrons scattered by silver with surface contamination.

The sixth Australian Spectroscopy Conference will be held in Brisbane in 1967.

BRITISH AID TO DEVELOPING COUNTRIES

A WHITE PAPER from the Ministry of Overseas Development*, outlining the work of the new Ministry, describes the policies by which the British Government

proposes to be guided and the ways in which it hopes to help to meet the needs of the developing countries, without, however, specifying the extent of Britain's aid in particular periods. Successive chapters outline motives and objectives, the pace of overseas development, the transfer of resources and Britain's capacity to help—in

* Ministry of Overseas Development. *Overseas Development: The Work of the New Ministry*. (Cmd. 2786.) Pp. 74. (London H.M.S.O., 1965.) 5s. 6d. net.

which the Department of Technical Co-operation had laid firm foundations. However, it does not really meet the criticism which has come from the Overseas Development Institute, or from the Estimates Committee in its tenth report for the session 1963-64. Mr. R. Carr, then head of the Department of Technical Co-operation, had indicated that Britain's contribution, £190 millions in 1964, would rise to about £220 millions, and since the White Paper was published it is understood that this figure will probably be increased to £250 millions.

The White Paper makes scarcely any reference to the application of science and particularly of research, and this weakness, exemplified notably in the disbandment of the Overseas Research Council, therefore persists. The initiatives in technical assistance which are being taken in the economic services seem a little inadequate. Certainly, it is unfortunate that in a statement on the White Paper in the House of Commons on August 3 the Minister should have been so petulant and inclined to make a party issue of a matter which has the support of all parties and for which Mr. Carr had laid such good foundations. Mrs. Castle said that the levels of expenditure on aid would be contained in the national plan. It was proposed to establish a careers service in the Ministry for a corps of specialists directly employed by the Ministry who would normally be on loan overseas. The Ministry was also setting up an Overseas Service Pensions Fund to provide pension rights for persons serving overseas for which such provision was not at present made.

Much in the White Paper supplements an earlier statement from the Department of Technical Co-operation in 1963, but further chapters deal with the lines of future policy, the new terms of aid, the private sector and the Commonwealth Development Corporation, the management of aid, and with what are described as "new initiatives in technical assistance", including recruitment and voluntary service, economic services, education, training and public health. It is emphasized that the Ministry would like to see it widely accepted in Britain that a professional career should normally include a period of work overseas in a developing country. The Government has decided, therefore, that in fields of recruitment where it is important to ensure that British help is available, the home establishments of Government departments and public bodies should be strengthened so as to make it possible to release people more readily. Discussions with other Government departments and the University Grants Committee have shown that there is scope for strengthening certain establishments and that the organizations concerned are willing to co-operate. A total of at least 400 posts will be added for this purpose to home establishments, in Government departments, universities, technical colleges, etc.

On service overseas by volunteers, the White Paper, noting that the number of such volunteers is expected to

rise from 1,400 in the autumn of 1965, to 1,800 in 1966, points out that it is important to widen the range of work which volunteers are doing and to draw them from wider sections of our society. On the economic services, more economists and statisticians are being supplied for periods of service overseas, directly attached to Governments; it is hoped to increase this number by the recruitment measures just described. A survey of British universities is being undertaken to learn more about the number and type of economists interested in, and available for, work overseas; the supply of such people will be increased by a new Institute of Development Studies in accordance with the recommendation of the Bridges Committee in 1962. Up to 1,000 non-university teachers are to be recruited in 1965 and almost £200 millions a year has been spent on the supply of teachers under the Overseas Service Aid Scheme alone. The provisions of the Overseas and Development Service Bill will help to increase new recruitment and retain the services overseas of British staff employed other than by Governments. The Commonwealth Teacher Training Bursary Scheme has been stepped up to 500 and will be increased to 550 next year. The number of students and trainees coming to Britain under the Ministry's programme has risen from just more than 2,000 in 1962-63 to nearly 2,800 in 1964-65.

Under the terms of aid, the White Paper refers to the decision to make development loans free of interest where appropriate. It is claimed that the new structure under the Ministry of Overseas Development has strengthened Britain's work on aid in various ways and, after detailing the extent of British aid, there is a brief appendix on the organization of the Ministry. The objective of Britain's aid programme is to help developing countries in their efforts to raise standards of living. Its basis is accordingly a moral one, but it is recognized that provision of aid is to Britain's own long-term economic advantage and that she gives aid because, in the widest sense, it is believed to be in her interests to do so as a member of the world community. British or any other aid is most effective where it forms an integral part of a coherent and co-operative effort to implement a well-prepared development plan.

The White Paper is well written and cogently argued. It directs attention to such obstacles to the development of the poorer countries as the shortage of professional and technical personnel, which in many countries had been even more serious than shortage of foreign exchange in inhibiting development. It also notes the difficulties caused by the accelerated growth of population and, as a consequence of economic and demographic trends, a general failure to find productive employment for the labour force. Its silence in regard to scientific research is its outstanding defect, and from this it is apparent how vulnerable some of the proposals are to the incidence of the Government's new measures of restricted expenditure.

SOLAR MOTION AND SUNSPOT COMPARISON

By DR. ROBERT M. WOOD*

Assistant Director, Research and Development, Douglas Missile and Space Systems Division, Santa Monica, California

AND

PROF. KARL D. WOOD

Aerospace Engineering Sciences Department, University of Colorado, Boulder

SEVERAL attempts have been made to associate the position of the planets with the 11.1-year cycle of solar activity¹. This article presents some preliminary results of a solar dynamic investigation based on classical dynamics. The inertial frame for bodies in the solar system is the centre of mass of the solar system, not the

centre of the Sun². It is known that the centre of the Sun can be greater than one solar radius distant from the solar system centre of mass if Jupiter and Saturn are in the same general direction in space³. This motion of the Sun with respect to the solar system centre of mass will lead to forces on and in the Sun which vary with time and heliographic position. Although the spatial relationships between the Sun and the solar system centre of mass

* Mailing address: Dr. R. M. Wood, 580 Swarthmore Avenue, Pacific Palisades, California 90272.

have been examined and reported, we are aware of no systematic investigation of the attendant velocity, acceleration, or jerk, an accepted term for rate of change of acceleration.

To accomplish such an investigation, the appropriate three-dimensional vector operations were coded for use with the IBM 7094 computer, using an autogenerating ephemerides sub-routine as an input. For example, the position, velocity, acceleration, and jerk of the Sun are given, respectively, by:

$$\begin{aligned}\vec{cmr}_1 &= - \sum_{i=2}^{10} (m_i) \frac{\vec{r}_{1i}}{|\vec{r}_{1i}|^3} \\ \vec{cmv}_1 &= - \sum_{i=2}^{10} (m_i) \frac{\dot{\vec{r}}_{1i}}{|\vec{r}_{1i}|^3} \\ \vec{cma}_1 &= - G \sum_{i=2}^{10} (m_i) \frac{\vec{r}_{1i}}{|\vec{r}_{1i}|^3} \\ \vec{cmj}_1 &= - G \sum_{i=2}^{10} m_i \left(\frac{\ddot{\vec{r}}_{1i}}{|\vec{r}_{1i}|^3} - \frac{3(\dot{\vec{r}}_{1i})(\dot{\vec{r}}_{1i})}{|\vec{r}_{1i}|^4} \right)\end{aligned}$$

where \vec{r}_i and $\dot{\vec{r}}_i$ are outputs of the autogenerating ephemerides sub-routine, a pre-subscript refers to the co-ordinate system, and a post-subscript refers to the body in question ($i = 1$ for Sun, $i = 2$ for Mercury, etc.). The body mass is given by m_i , position by \vec{r}_i , and acceleration by $\ddot{\vec{r}}_i$, and G is the universal constant of gravitation. Pluto ($i = 10$) was omitted because its influence is negligible for the calculations performed.

The four large outer planets (Jupiter, Saturn, Uranus, Neptune) are the most important in determining the position of the Sun⁴, whereas the three closest inner

Table 1. RANGES OF SOLAR DYNAMIC QUANTITIES

Planets	Position (10^8 m)	Velocity (m/sec)	Acceleration (10^{-7} m/sec ²)	Jerk (10^{-14} m/sec ³)
All	0-15	9-16	1.4-2.9	0-2.8
Outer	0-15	9-16	1.7-2.5	0.8-0.4
Inner	0-0.01	0.01-0.2	0-0.6	0-2.4

These ranges were obtained by the examination of 100 years of output most of it at 8-day intervals. IBM 7094 running time is about 1 min per decade. Note the increasing importance of the inner planets with each successively higher time derivative.

planets (Mercury, Venus, Earth) are the most important in determining the jerk of the Sun. Table 1 illustrates this point by summarizing the ranges of the magnitudes of these dynamic quantities. It is particularly noteworthy that the fluctuation of the acceleration due to all the planets is approximately twice that due to the outer planets only; furthermore, the inner planets predominate in their influence on the jerk. Although it is not known whether the jerk itself is a physically important quantity, it represents a useful function which is related to rate of change of force.

The solar acceleration and jerk vectors can be usefully described by three scalars each: magnitude, component along the Sun's axis, and the longitude. The latter is defined as that angle between the planes defined by the zero longitude vector and the Sun's axis of rotation, and the vector of interest and the Sun's axis. The zero longitude vector is essentially fixed in direction in inertial space and lies at the intersection between the plane of the solar equator and the plane of the ecliptic.

The jerk longitude in inertial heliographic co-ordinates is plotted for the beginning of sunspot cycle 17 (1933) and cycle 18 (1944) in Fig. 1.

The detailed similarity of the patterns for the times beginning with 1933 and 1944 does not occur at any intermediate times, although space prevents a display of this point. The jerk along the Sun's axis and the magnitude of the jerk also repeat in a similar fashion, and all these quantities have patterns which repeat with the same period

Fig. 1. Jerk longitude during portions of cycle 17 and cycle 18. The longitude is measured in the plane of the solar equator from the ascending node of the intersection between the plane of the solar equator and the ecliptic. The time axes, shown in Julian days, are displaced by 4,085 days. The 1933-34 time axis goes with the solid curves and the 1944-45 time axis with the dashed curves. The pattern separation is determined to be 4,047 days.

for cycles 19 and 20. Moreover, although the acceleration has a maximum approximately every 11.86 years (due to Jupiter) the fine structure of the acceleration due to the inner planets has the same repetition period as the jerk. Careful measurements of accurate curves indicate a separation between the patterns of 4,047 days, corresponding to 11.08 years. The average length of the solar sunspot cycle from Waldmeier⁵, using maxima from 1610 to 1960, is 11.04 ± 0.25 years, and using minima is 11.08 ± 0.20 years. This correspondence, while not conclusive, seems unlikely to be accidental.

Fig. 2 shows the comparison between smoothed sunspot Wolf number and the rate of change of jerk longitude. The Wolf number is the daily count of the number of spots plus ten times the number of sunspot groups, and is roughly proportional to the total sunspot area. The similarity of the curves is interesting. The use of rate of change of jerk longitude followed considerable examination of other dynamic function comparisons, namely, acceleration magnitude, jerk magnitude, axial components of jerk and acceleration, and longitude of acceleration. The Wolf number peaks of 1947 were selected to illustrate a case of favourable comparison. Since for other years the similarity of the curves is weaker, this suggests that the rate of change of jerk longitude is not the main variable responsible for an effect on solar activity, if indeed such a causal effect does exist.

There are several ways in which the Sun's motion and attendant accelerations, forces, or their rate of change may trigger solar activity. Three typical ones are: (a) small photosphere velocities could result in Coriolis terms leading to cyclones and anticyclones; (b) the very unstable convective region several hundred km below the visible surface could be influenced by acceleration, leading to different buoyant forces⁶; (c) dynamic effects could push the material associated with strong magnetic fields through the solar surface, as in Babcock's theory⁷. Such mechanisms all seem plausible.

If the motion of the Sun as determined by the gravitational forces of the planets is a causal element for solar activity⁴, then many observed facts about solar activity could be explained. The alternation of sunspot polarities with each cycle, the decrease in latitude of activity as the cycle progresses, the multiplicity of cycles⁸, the east-west asymmetry of activity, and the observed recurrence of active regions fixed in inertial space all require explanation. By demonstrating a physical link between solar dynamics and solar activity, a more comprehensive understanding of solar physics could be realized. This could ultimately lead to realistic solar activity prediction.

In conclusion, the following points can be clearly stated: (a) the influence of the inner planets on the fluctuation of the acceleration of the Sun in inertial space is as important as that of the outer planets; (b) the short-time

Fig. 2. Comparison between Wolf number and jerk longitude rate for 1947. A 27-day moving average for Wolf number has been used to reduce greatly the effects of solar rotation as seen from the Earth. The rate of change of jerk longitude is the slope of curves like those of Fig. 1. The average solar rotation rate is shown for reference.

acceleration and jerk patterns are repetitive with a clear 11.08-year period, agreeing well with the mean sunspot cycle.

STRATOSPHERIC TRANSPORT OF VOLCANIC DUST INFERRED FROM SOLAR RADIATION MEASUREMENTS

By DR. A. J. DYER and B. B. HICKS

C.S.I.R.O. Division of Meteorological Physics, Aspendale, Victoria, Australia

RECENTLY, a number of authors have reported observations of volcanic dust in the southern hemisphere following the eruption of Mount Agung, Bali (8° S., 115° E.), on March 17, 1963. Hogg¹ discussed several optical effects observed at Mount Stromlo and elsewhere. Moreno and Stock² measured extinction effects at Cerro Tololo, Chile. Mossop³ obtained dust samples from aircraft flights at a height of 20 km in latitude belts 15°-35° S. and 40°-45° S. Flowers and Viebrock⁴ have reported an anomalous decrease in solar

radiation at the South Pole and also at Mauna Loa, Hawaii.

In the northern hemisphere, Meinel and Meinel⁵ have estimated the height of the dust layer over Tucson, Arizona, to be 17.8 km in late 1963.

These various accounts contain some features of interest to the meteorologist concerned with atmospheric transport on a global scale. It appears that the volcanic dust moved toward the South Pole in the lower stratosphere at such a rate that the initial detection in middle

latitudes occurred after 5-7 weeks and the maximum concentration appeared after about 4-6 months. These findings bear a remarkable similarity to observations at 38° S. of the arrival of fission debris following the atomic tests in equatorial regions in 1958-62 (refs. 6 and 7).

A very extensive record of solar radiation data has been continuously maintained since 1959 at this laboratory. This has been examined to see if information could be deduced concerning the movement of the dust over a number of years. Similar investigations following the Krakatoa, Mount Pelée, Katmai and other explosions suggested that absorption of the direct solar beam by the dust layer might be observable for several years⁸⁻¹¹.

The data used exist in the form of continuous chart records of the total radiation T and the diffuse radiation D falling on a horizontal surface. These observations are made with Kipp and Zonen pyranometers periodically calibrated against a Linke Feussner pyrheliometer. From the chart records, 'clear' days were selected, that is, days for which there was no evidence of cloud within 1 h of noon, and the maximum values about noon of total and diffuse radiation noted. On the average seven 'clear' days were available for each month with slightly more in summer than in winter.

The direct solar radiation, I , at normal incidence, can be readily calculated from $I = (T - D)/\cos \zeta$ where ζ is the zenith angle. Subsequent analyses were then carried out in terms of two-month averages.

The data for the years 1959-62 were used to establish the norms \bar{T} , \bar{D} and \bar{I} for each two-month period. Fig. 1 presents a plot of the quantities D/\bar{D} , I/\bar{I} , T/\bar{T} and D/\bar{T} for 1959-65. The time of the Bali eruption is indicated.

It is obvious that some remarkable effects occurred in the radiation levels during 1963 and to a lesser extent in 1964 and 1965. In the light of observations elsewhere it is plausible to associate this with the presence of a layer of volcanic dust from the Bali eruption. The gradual removal of the dust over a period of several years is evident.

The maximum effect occurred during July-August of 1963 when the direct solar radiation was reduced by 24 per cent. A reduction of 16 per cent occurred during July-August of 1964 and there is a suggestion of similar behaviour in 1965.

The most spectacular feature appears in the diffuse radiation record which shows twice normal values during July-August 1963 and continues to show abnormally high values in 1964 and 1965.

The total radiation values show a significant, but less-obvious, reduction in 1963 and 1964. The information contained in Fig. 1, if taken at face value, would indicate that, of the radiation removed from the direct solar beam, more is scattered in a forward than in a backward direction. This would imply only a minor modification of climate as a result of scattering by the dust layer, even when such dramatic effects are evident in the direct and diffuse radiation.

It is clear, however, that the 'signal-to-noise ratio' of the total radiation data in Fig. 1 is not very high. This is caused partly by the presence of pollutants in the urban atmosphere and partly by the use of data from routine observations instead of a specifically oriented experiment. A similar analysis of higher quality data would materially assist the foregoing considerations.

From the point of view of using the volcanic dust as a tracer of atmospheric motions, it is necessary to estimate the amount of dust present at various times.

The change in the direct solar beam dI' along an element at slant path dl is given, in simple scattering theory, by:

$$dI' = -knI'dl - k_0n_0I'dl$$

where k is a scattering coefficient and n is the concentration of dust particles in a thin layer. The term $k_0n_0I'dl$ is the reduction due to scattering by aerosols normally present.

Fig. 1. Deviations from the mean of the diffuse, direct and total solar radiation and the contribution of scattered radiation to the total, 1959-65.

Introducing the Earth radius R , the solar zenith angle ζ , the height of the dust layer h and its depth Δh , we have on integration:

$$\ln(I/I_0) = -kn \left\{ \sqrt{(R+h)^2 - R^2 \sin^2 \zeta} \right\}_h^{h+\Delta h} - C$$

where I_0 and I are the values of I' outside the atmosphere and at the Earth's surface respectively. C refers to the integral of k_0n_0dl taken throughout the atmosphere. Making the simplifying approximation $R \gg h \gg \Delta h$, we have:

$$\ln(I_0/I) = kn\Delta h/(\cos^2 \zeta + 2h/R)^{1/2} + C$$

\bar{I} , as previously defined, is the average value of I in the absence of volcanic dust so that $\ln(I_0/\bar{I}) = C$ and hence:

$$\ln(\bar{I}/I) = kn\Delta h/(\cos^2 \zeta + 2h/R)^{1/2}$$

Since $n\Delta h$ represents the total number of dust particles in a vertical path we can, by assuming k constant, use the quantity $(\cos^2 \zeta + 2h/R)^{1/2} \ln(\bar{I}/I)$ as an index of the amount of dust present at any time. We may, in fact, expect k to change slowly with time owing to the gradual removal of the larger particles. The term $2h/R$ is only important when the Sun is very close to the horizon. At all other zenith angles, $(\cos^2 \zeta + 2h/R)^{1/2}$ reduces to $\cos \zeta$.

In Fig. 2 the quantity $(\cos^2 \zeta + 2h/R)^{1/2} \ln(\bar{I}/I)$ is plotted from the present data and for the South Pole data of

Fig. 2. The dust content of the atmosphere above Aspendale and the South Pole following the eruption of Mt. Agung on March 17, 1963

Flowers and Viebrock^{4,5}. In the latter case, a dust layer altitude of 10 km has been assumed where necessary.

The first major arrival of volcanic dust is seen to occur during July–August of 1963 at 38° S. and during January–February of 1964 at 90° S. At almost the same times in the following year a new influx of dust is apparent at both latitudes, indicating a pronounced seasonal effect in the poleward stratospheric transfer. The existence of an enhanced ‘winter’ transfer revealed in 1964 would no doubt have contributed to the initial arrival of the volcanic dust in 1963. The indications of Fig. 2 are supported by the occurrence of vivid sunsets over Southern Australia during the winters of 1963 and 1964, and their reappearance at reduced intensity during the present 1965 winter. Similar seasonal effects were observed in 1884 and 1885 following the Krakatoa eruption in 1883 (ref. 8).

Time-lags of similar amounts between temperate and polar latitudes have been observed in studies with other

tracers. The maximum in total ozone occurs at 38° S. in September, at 54° S. in October and at 75° S. in December¹². The maximum in radioactive fall-out in rain occurs over southern Australia during November–December¹. All these tracers have in common that they originate in equatorial regions. Ozone is also produced at other latitudes, but in reduced amounts.)

It is clear that stratospheric transfer processes from equator to pole involve times of the order of five months to middle and eleven months to polar latitudes. Whether these take the form of mean motion or eddy diffusion, or some combination of both, cannot be determined from the present studies. However, for the South Pole data Flowers and Viebrock have commented that the sudden arrival of dust in November 1963 coincided with a change in the stratospheric circulation from circumpolar to meridional. The volcanic dust observations are consistent with the presence of an equatorial reservoir with gradual depletion by enhanced poleward transfer during the winter.

The different times of occurrence of the maxima of the various tracers are probably associated with the different heights at which the tracers occur and at which the transport takes place. A complete understanding, however, requires considerably more detailed information than we have at present.

We thank Dr. Herbert J. Viebrock for permission to use his unpublished results, and Mr. B. G. Collins for his assistance in analysing the Aspendale radiation data.

EXPERIMENTAL OBSERVATIONS ON THE STRUCTURE OF COLLISIONLESS SHOCK WAVES IN A MAGNETIZED PLASMA

By DR. J. W. M. PAUL, L. S. HOLMES, DR. M. J. PARKINSON and J. SHEFFIELD
U.K. Atomic Energy Authority Research Group, Culham Laboratory, Abingdon, Berkshire

THIS article reports measurements of the structure of shock waves propagating through a plasma in a direction perpendicular to an initial magnetic field. The shock wave is produced by a fast linear ‘Z-pinch’ between electrodes with 100 cm separation in a fused silica tube of 50 cm diameter. The applied electric field of 320 V/cm produces an axial current which rises to 300 kA in 0.7 μsec, and flows in a thin annular layer (~1 cm). The resulting pinch forces drive this skin current radially inwards at a velocity exceeding the Alfvén velocity for the undisturbed plasma. This rapid radial compression generates an imploding shock wave which propagates ahead of the driving current layer.

The radial distribution of electron density in the initial plasma has been measured by using a double Langmuir probe and by infra-red interferometry. For the particular case of a hydrogen plasma with central electron density $n_0 = 7 \times 10^{14} \text{ cm}^{-3}$ and initial axial magnetic field $B_{z0} = 1.2 \text{ kG}$, the total density (ions and neutrals) has also been measured. This was obtained from the measured velocity of propagation of a low-frequency, small amplitude, magnetosonic wave. The deduced degree of ionization is more than 85 per cent for the central 20 cm diameter.

The plasma collapse has been examined in detail for the foregoing conditions by using magnetic probes. The shock front, a sharp jump in axial magnetic field strength, is clearly separated from the thin skin current (Figs. 1 and 2). For most of the implosion the Alfvén Mach number (shock velocity (V_s) /initial Alfvén velocity), $M_A = 2.5$. The measured magnetic fields have been compared with numerical computations in which the plasma is treated in the magneto-hydrodynamic (MHD) fluid approximation¹. With this model the shock structure broadens rapidly as viscous effects increase. If viscosity is omitted the structure steepens as the electron temperature rises and resistivity decreases. These structure effects, which disagree with the experimental results, are avoided by introducing into the computation an artificially fixed shock width². Good agreement is then obtained between the experimental and computed dynamics if it is assumed that the neutral gas in the outer 10 cm takes part in the collapse (Figs. 1 and 2).

The structure of the shock front has been examined in detail using magnetic probes of diameter down to 0.9 mm and a coaxial double electric probe with an effective tip of 0.25 mm and variable electrode separation. The electric probe records the radial voltage (V_r) through the shock

front. For the foregoing conditions ($M_A = 2.5$), the radial voltage rises in less than 6 nsec as the shock moves on to the tip of the electric probe. The magnetic probe records a coincident but slightly slower rise of magnetic field. Typical oscillograms are shown in Fig. 3. The measured radial voltage (V_R) and change of magnetic field ($B_z - B_{z0}$) in the shock front are plotted in Fig. 4a against time for 9 cm radius. As the measured shock velocity is sensibly constant at 2.5×10^7 cm/sec, Fig. 4 also represents the spatial variation.

The measured shock width (1.4 mm) is appreciably shorter than the appropriate ion-ion and ion-neutral mean free paths (5 cm and 2.5 cm, respectively). Consequently, collisional viscosity can be neglected as reported previously³. Resistive dissipation through the azimuthal current in the shock front, which is the only other collisional process (electron-ion collisions) capable of sustaining such a shock⁴, cannot be eliminated by such a simple criterion. The measured 6-nsec rise time of the voltage is less than two electron-ion collision times. The latter is calculated for the region behind the shock by assuming that the shock heating goes entirely to the electrons, raising their temperature to 50 eV. It is unlikely that this energy can be lost from the shock front in such a short time. As several collisions are required within a collision-dominated shock front it is probable that a collisionless resistivity, such as is provided by turbulence from electron drift instabilities^{5,6}, is important. The measurements indicate an electron drift velocity of about 10 per cent of the predicted electron thermal velocity. This would correspond to the critical drift velocity for instability given by Stringer⁷ if $T_i \sim 0.1 T_e$. The shock width is about $7(c/\omega_{pe})$ for the initial conditions. This is appreciably less than $25(c/\omega_{pe})$ found by Adam⁸. As further evidence for collisionless interaction, the measured rise time of 13 nsec in deuterium at about the same mass density and M_A corresponds to only half an electron-ion collision time while the shock width is about $10(c/\omega_{pe})$.

The change in directed energy of an ion passing through the shock front (considered at rest) is $\Delta W = \frac{1}{2} M[V_s^2 -$

Fig. 3. Typical oscillograms of V_R and dB/dt at 9 cm radius for $M_A = 2.5$. Electric probe tip separation, 1 cm

Fig. 4. Structure of magnetic field and electric potential through the shock front for $M_A = 2.5$ (top); $M_A = 3.7$ (bottom)

Fig. 1. Radial variation of B_z and B_θ at 0.9 μ sec from a magnetic probe of 7 mm diameter and from computation with a 7 mm shock width

Fig. 2. Space-time 'streak' diagrams of plasma collapse from magnetic probes and computation

$(V_s - V_p)^2]$, where M is the ion mass and V_p is the plasma velocity behind the shock (laboratory co-ordinates). The latter has been derived from the measured magnetic field profiles using the fact that (B_z/n_0) is constant on both sides of the shock (though not within it). The measured azimuthal electric field E_θ behind the shock also provides a measure of $V_p (=E_\theta/B_z)$. The measured voltage across the shock is such that the ratio $R = eV_R/\Delta W = 1$. This means that the ion motion through the shock is entirely accounted for by electric field effects. By implication, the change of ion pressure across the shock is negligible. The measured V_R can be accounted for, in accordance with the generalized Ohm's law⁹, by the known force ($J_\theta \times B_z$) acting on the electron current (J_θ) and the predicted electron pressure gradient.

With resistivity (either collisional or not) as the only dissipative mechanism, continuum theory predicts the occurrence of a discontinuity (iso-magnetic jump) in the fluid velocity within the shock structure for M_A greater than a critical value $M_A^* \sim 3$ (ref. 4). Physically beyond this limit slip of field and plasma (resistive dissipation) alone cannot provide sufficient dissipation of energy. Theories based on particle orbits predict the occurrence of multiple streaming of the ions above a similar limit⁸.

Experimentally M_A is increased by reducing the initial magnetic field. For $M_A = 2.5$ and 3.7 the initial plasma density and the shock velocity are effectively the same. However, at $M_A = 3.7$ the shock has a clear double structure (Fig. 4b) with the sharp transition preceded by a broad one (~ 1.5 cm) corresponding to $2c/\omega_{pi}$. This broad feature of the structure appears for $M_A \geq 3$ over a range of parameters and is interpreted as evidence for the additional mechanism required theoretically. The

Fig. 5. Structure of magnetic field through the shock front for $M_A = 2.5$, 3.7 and 6.3. (For the latter $B_0 = 0.48$ kG, $n_0 = 4.5 \times 10^{14}$ cm $^{-3}$, $V = 2.8 \times 10^8$ cm/sec)

measured voltage across the shock front again corresponds to $R = 1$, implying that the electrons are heated.

At still higher M_A , the broad structures forward and to the rear of the sharp transition become dominant and at $M_A = 6$ (Fig. 5) the sharp transition is absent. The total structure is then so broad that cylindrical effects are important.

The broad additional feature is shorter than the ion-ion mean free path but is comparable with the ion-neutral mean free path. Even so, this latter mechanism can be neglected because at least five such collisions are required to collect the undisturbed ions (> 80 per cent ionized). Electron thermal conductivity, another relevant collisional mechanism¹⁰, is made negligible by the presence of the axial magnetic field¹¹. Consequently, all collisional mechanisms appear to be eliminated for $M_A > M_A^*$.

Of the many theories of collisionless shocks, only a few are valid for $M_A > M_A^*$. Theories involving ion-ion streaming instabilities^{12,13} can be eliminated because they

predict a sharp transition of width $L \sim \frac{2\pi V_s}{\omega_{pi}}$. The theory of Colgate¹⁴, involving Landau damping of electron oscillation, also predicts a sharp transition with $L \sim \frac{c}{\omega_{pe}}$. Auer

*et al.*¹⁵ treat the problem of ion streaming without instabilities but derive an effective entropy increase from ion gyration phase mixing and assume that the electrons are not heated. This approach leads to a time-dependent

structure with $L \sim \frac{c}{\omega_{pi}} M_A$ (ω_{pi} for compressed plasma) and $R = 0.25$ (for $M_A = 6$). Carmac *et al.*¹⁶ describe a model based on non-linear wave-wave interaction within a front of width $L \sim \frac{2c}{\omega_{pi}}$ for $M_A \sim 4$ but steepening with increasing M_A . The particular analysis, though not the mechanism, is limited to low M_A ($< M_A^*$). Although no explicit prediction is made, it is reasonable to assume that the waves involved ($\omega \gg \omega_{ci}$) heat the electrons and consequently $R = 1$. These values of L and R are comparable with those of the broad feature, but the dependence on M_A appears inconsistent.

Experimental imperfections make it possible that the magnetic field makes a small angle ($\theta > \sqrt{\frac{m_0}{M_A}} \sim 1^\circ$) to the shock front. For the foregoing conditions with $M_A > M_A^*$ this leads to a shock structure^{17,18} more than an order of magnitude shorter than that observed and consequently has been neglected.

In summary, at low Mach numbers ($M_A < 3$) the results indicate that a resistive shock is formed which probably involves collisionless turbulence. Above the predicted critical M_A (~ 3) the observed change of structure is interpreted as due to an additional, but unidentified, collisionless mechanism. None of the present theories of shock structure gives convincing agreement over the range of observations, but some can be eliminated.

We thank Dr. R. J. Bickerton for his advice and Mr. C. A. Steed for his assistance.

PLEISTOCENE GLACIAL-MARINE ZONES IN NORTH ATLANTIC DEEP-SEA SEDIMENTS

By DR. JOHN R. CONOLLY* and DR. MAURICE EWING

Lamont Geological Observatory of Columbia University, Palisades, New York

SINCE Bramlette and Bradley¹ first described glacial marine sediment zones in deep-sea cores across the North Atlantic, there has been no further attempt to use these zones as criteria for interpretation of Pleistocene climates. The occurrence of glacial erratics in the North Atlantic has been described by several authors²⁻⁴. One of the most recent accounts was given by Pratt⁵, who described erratic boulders of granite, schist, diorite and quartzite from cores and dredges on the Great Meteor Seamount. These accounts indicate that icebergs floated much farther south in the North Atlantic during the cold

periods of the Pleistocene, dropping considerable continental material as far south as 30° N.

An investigation was made of the occurrence of ice-rafted material in the Lamont cores from the North Atlantic to find cores in pelagic sediment which contained large variations in the vertical distribution of ice-rafted debris. In general all cores taken in pelagic sediment north of 50° N. contained abundant glacial debris. In many areas near Labrador, Greenland and Iceland there was so much glacial debris that obvious variations in the amount of intensity of ice-rafting could not be measured. Farther south, cores described by Ericson *et al.*⁷ consist of zones of sediment containing abundant ice-rafted grains.

* Present address: Department of Geology, Louisiana State University, Baton Rouge, Louisiana

Cores taken south of 35° N. contain little or no ice-rafted grains. Hence it was decided to examine the variation in ice-rafted material in the cores between 40° and 60° N., particularly since Ericson *et al.* had already shown that they contained zones consisting of different Foraminifera assemblages deposited during cold and warm periods of the Pleistocene. The zones delineated by Ericson *et al.* can also be defined using the relative abundance of ice-rafted detritus present in the cores.

The amount of ice-rafted detritus present in the sand fraction of 13 cores taken from the North Atlantic (Fig. 1) previously described by Ericson *et al.*⁷ was estimated at intervals down the cores (Fig. 2) by examination of the sand fraction under a binocular microscope. The cores lie between latitudes 40° and 60° N and consist almost entirely of pelagic sediment containing varying percentages of pelagic organisms. Cores A157-5 and A180-14 were taken near the edge of the Sohms Abyssal Plain and contain one or two very thin quartz silt beds, presumably deposited by turbidity currents; but the rest of the sediment in these two cores is mainly pelagic. The remainder of the cores is located in positions in the deep-sea floor favourable for pelagic deposition.

In general, the sand fraction consists mainly of tests of pelagic Foraminifera mixed with ice-rafted sand and minor amounts of volcanic ash. The ice-rafted detritus is easily identifiable, as it characteristically consists of very poorly sorted, and mainly angular, sand and pebbles of a variety of mineral and rock types. The size, poor sorting, general angularity and wide lithological range of this detritus that occurs in pelagic sediment, far from

land, indicate that it has dropped from melting ice. Many of the large pebbles are striated or faceted and large quartz grains are commonly frosted and pitted. Quartz is most abundant and commonly makes up 50-70 per cent of the sand fraction. Pebbles of granitic, gneissic, regional metamorphic and sedimentary rocks of all kinds make up the bulk of the fraction coarser than 1 mm.

Black pumice and brown and black glass occur associated with ice-rafted sand in cores from the eastern North Atlantic. Since the amount of black volcanic detritus present bears a constant relation to the amount of poorly sorted ice-rafted sand, it must also be ice-rafted. The black pumice and glass are most abundant in cores taken close to Iceland (Fig. 1), as has been previously noted by Ericson *et al.*⁸, and the amount of black pumice decreases southwards, indicating dilution of this volcanic detritus from Iceland with detritus from eastern Greenland and the British Isles. In the western North Atlantic, quartz is less common and makes up only 30-50 per cent of the ice-rafted sand. Large quantities of hornblende and garnet are particularly characteristic of the sand in cores A157-5 and A157-6.

The amount of ice-rafted sand present increases from a few grains in the southernmost cores to 20-30 per cent of the total volume of sediment in the glacial marine zones in cores SP10-1 and SP9-3. The variation in the percentage of ice-rafted detritus in the sand fraction at intervals down the cores (Fig. 2) can be interpreted as a measure of the effects of climate on deposition. Zones containing a relatively high percentage of ice-rafted detritus correlate very closely with zones containing

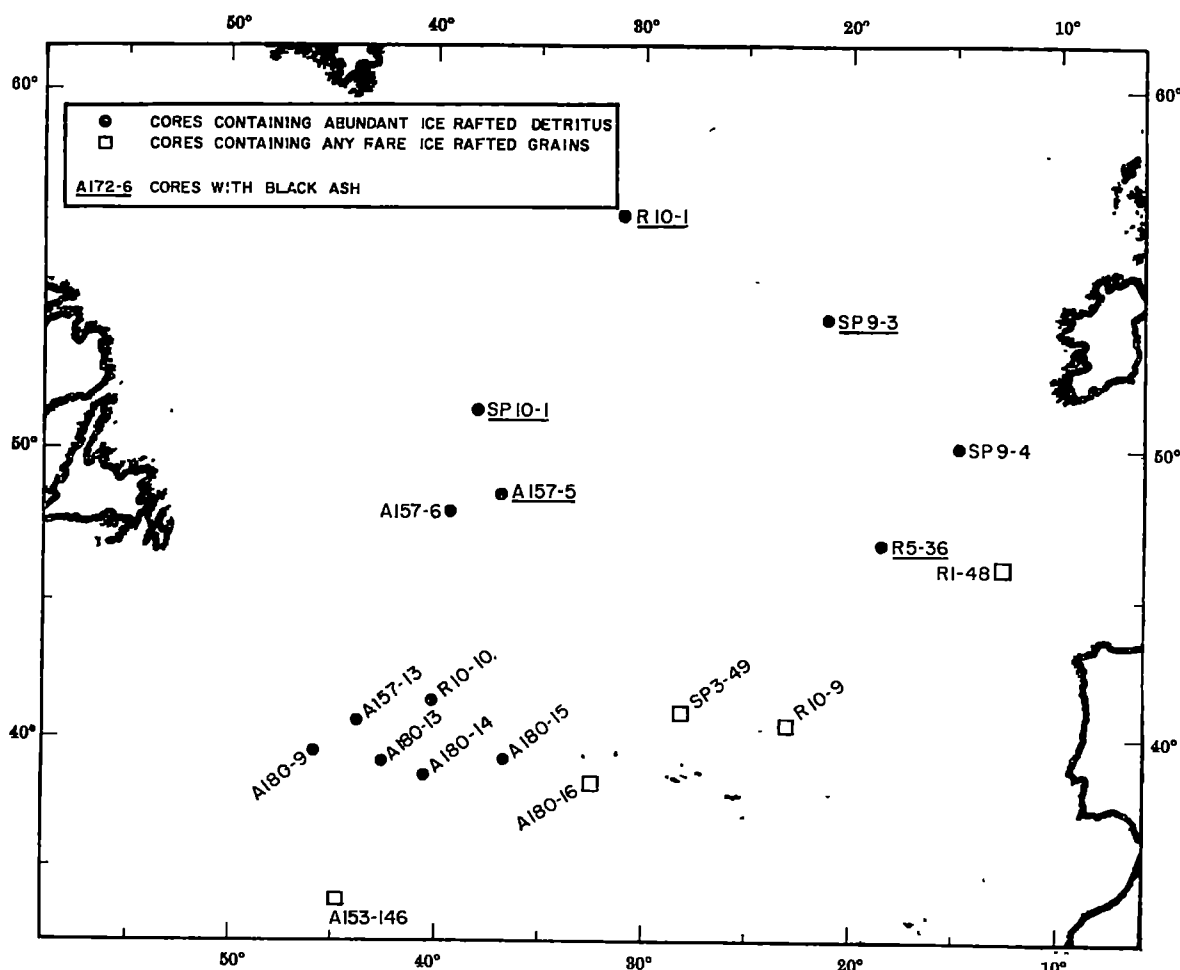

Fig. 1. North Atlantic Ocean showing the location of cores described in this investigation with abundant ice-rafted sand and pebbles and the location of cores containing only rare ice-rafted grains. Cores in the north and north-western North Atlantic contain black pumice and brown and black glass probably derived by ice-rafting from near Iceland.

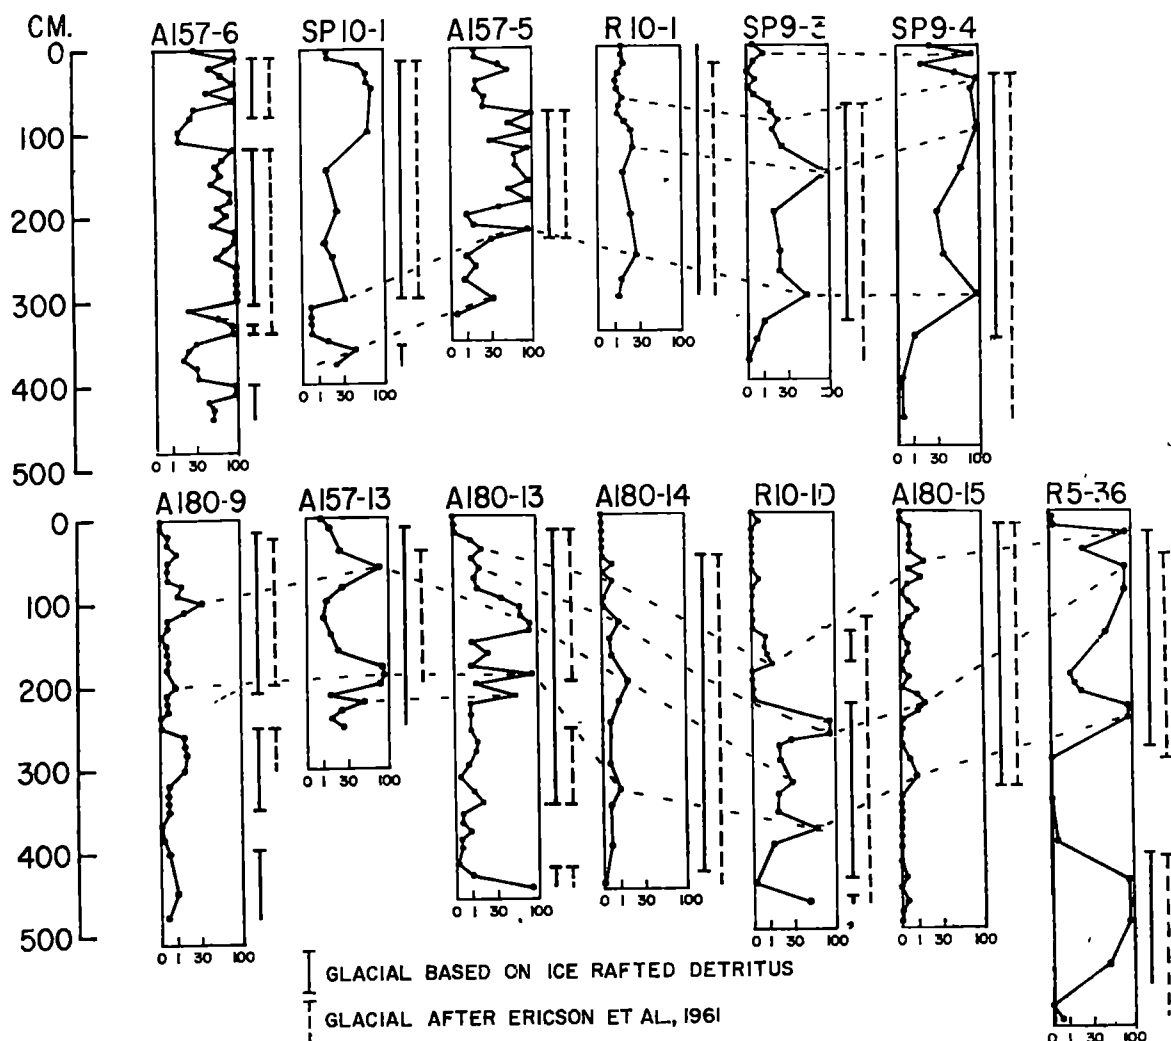

Fig. 2. The amount of ice-rafted detritus in the sand fraction is expressed as a percentage of the total sand fraction at intervals down 13 cores from the North Atlantic. Zones defined as glacial by Ericson *et al.* (ref. 7) in these cores can also be defined on the relative abundance of ice-rafted detritus. Tentative correlations are made between areas of cores containing high amounts of ice-rafted detritus. These areas may represent deposition during the major cold periods of the late Pleistocene.

colder-water foraminiferal assemblages described by Ericson *et al.*⁷

There is considerable fluctuation in the amount of ice-rafted detritus deposited during these cold periods, suggesting that it might be possible to determine the major cold and warm zones within each glacial by correlating areas representing maximum and minimum amounts of ice-rafted detritus in different cores across the North Atlantic.

If it is assumed that the zones which Ericson *et al.*⁷ considered to have been deposited during the last glacial (the period from about 11,000 to 60,000 years ago), and shown in Fig. 2, are correct, then it is possible to sub-divide fur-

ther this cold period on the basis of the relative abundance of ice-rafted detritus. For example, core R10-10 contains a distinct zone containing abundant ice-rafted detritus between 150 and 130 cm from the top of the core. This zone occurs between areas dated as $11,800 \pm 480$ and $15,820 \pm 200$ years old⁷ and probably contains ice-rafted detritus deposited during the last major glaciation of the last glacial period. Beneath this zone there are three more zones in which the sand fraction is made up almost entirely of ice-rafted detritus, suggesting that there were probably three more major cold periods during the last glacial period. Similar zones containing high amounts of ice-rafted detritus occur in many of the other cores and possible correlations between them are shown in Fig. 2.

These results indicate that the abundance and distribution of ice-rafted detritus in deep-sea cores in the North Atlantic could provide a powerful tool for delineating even minor fluctuations in the Pleistocene climate. Cores taken in pelagic sediment in the vicinity of cores R5-36, R10-10 and A180-13 in particular should contain easily determinable ice-rafted zones that might eventually lead to a better understanding of the fluctuations in climate and rates of sedimentation during the Pleistocene in the North Atlantic. Furthermore, it may be possible to delineate the Pliocene-Pleistocene boundary, using the first appearance of ice-rafted detritus in deep-sea pelagic cores as a criterion. The disappearance of ice-rafted

Table 1. LOCATION OF CORES USED FOR ICE-RAFTING DISTRIBUTION ANALYSES (Fig. 2)

Core	Latitude	Longitude	Water depth (metres)
A157-5	48° 35' N	36° 51' W	4,500
A157-6	48° 08' N	39° 20' W	4,500
A157-13	40° 34' N	43° 51' W	4,680
A180-9	39° 27' N	45° 57' W	4,060
A180-13	39° 08' N	42° 39' W	4,880
A180-14	38° 41' N	40° 40' W	5,020

SP10-1	51° 28' N	88° 04' W	3,695

detritus with depth occurs in sediment cores raised from the deep ocean floor surrounding Antarctica^{9,10} and occurs just beneath the Pliocene-Pleistocene boundary based on radiolarian assemblages¹¹.

So far, none of the cores taken in the North Atlantic ice-rafting area passes by continuous section through the Pleistocene and none has been identified as containing the Pliocene-Pleistocene boundary; but further attempts to take such cores are now in progress.

We thank D. B. Ericson, who kindly lent us samples of sand from Lamont cores. Important support for this work was provided by a Ford Foundation fellowship and a Fulbright travel grant for Dr. J. R. Conolly. This

work was also supported by the Office of Naval Research and by the U.S. National Science Foundation.

AN INFRA-RED INVESTIGATION OF THE EFFECT OF PRESSURE ON SILICA POWDERS, AS REVEALED BY DEUTERIUM OXIDE EXCHANGE

By F. H. HAMBLETON, Dr. J. A. HOCKEY and J. A. G. TAYLOR*

Department of Chemistry, Faculty of Technology, University of Manchester

IN recent years, infra-red spectroscopic techniques have been widely used to examine the surface properties of a variety of solids. The direct examination of finely divided solids is hampered by scattering of the incident radiation. This problem is often overcome by pressing self-supporting disks which have much higher transmission and, additionally, have a higher number of functional groups present in the beam. Infra-red investigations of the exchange properties of the surface hydroxyl groups present on silica, with deuterium oxide (D_2O) vapour, show that the high pressures used in disk formation can significantly alter the behaviour of the sample.

The pretreatment and surface properties of the re-hydrated 'Aerosil' used in the work recorded here have been described elsewhere¹. Disks were prepared from about 50-mg samples which were placed in a die and evacuated (on a conventional vacuum-line fitted with liquid nitrogen traps) to a pressure of 2×10^{-4} mm for 30 min. Two disks, RA2/5 and RA2/10, were formed by pressing at 5 tons/cm² and 10 tons/cm² respectively for 30 min. Two further disks, DA2/5 and DA2/10, were pressed after six-fold exchange in the die with saturated D_2O vapour (Norsk Hydro, purity 99.7 per cent); each contact lasted 120 sec and the sample was evacuated to 2×10^{-4}

* Present address: Unilever Research Laboratory, Port Sunlight, Cheshire.

Fig. 1. (1) Infra-red spectrum of original disk RA2/5; (2) spectrum after D_2O exchange; (3) infra-red spectrum of original powder RA—ordinate expanded 50 times; (4) spectrum after D_2O exchange

Fig. 2 (1) Infra-red spectrum of disk made from deuterated powder—DA2/5; (2) spectrum after H_2O exchange

mm mercury between each exchange, before final evacuation for 30 min at the same pressure.

The disks were mounted in a stainless-steel cell, similar to that described by Harrison and Lawrence², and spectra were recorded between 4,000 cm^{-1} and 1,500 cm^{-1} , using a Perkin-Elmer 125 double-beam grating spectrometer. The cell was connected to a vacuum line fitted with facilities for treating the sample, *in situ*, with water and heavy water vapour. Disks DA2/5 and DA2/10 were further treated with D_2O vapour to replace the surface OD groups lost during the transfer of the sample from the die to the cells.

The spectra of RA2/5 before and after D_2O exchange are given in Fig. 1; these show that an appreciable proportion of the 3,650 cm^{-1} hydroxyl band is unchanged; this proportion is even greater in the case of an RA2/10 disk. The absence of a peak at 3,737 cm^{-1} indicates that all the single hydroxyl groups are exchanged. Similar spectra for the unpressed RA2 powder are also shown; these indicate that a proportion of the unexchangeable hydroxyl groups are present in the powder.

That additional unexchangeable surface groups result from compression is illustrated by the spectra given in Fig. 2 for

Fig. 3. (1) Disk RA2/5 heated to 300°C; (2) after D₂O exchange; (3) disk RA2/5 heated to 450°C; (4) after D₂O exchange

Fig. 4. (1) Disk DA2/5 heated to 150°C; (2) after H₂O exchange; (3) disk DA2/5 heated to 300°C; (4) after H₂O exchange

DA2/5. As with the powder sample, there are unexchangeable hydroxyl groups, but in addition there are also OD groups resulting from exchange of the powder, characterized by a band at 2,710 cm⁻¹, which cannot be exchanged with water vapour. The intensity of this band

is greater for DA2/10 than for DA2/5. Control experiments show that all exchanges carried out on the disks are reversible. No change in the 1,640 cm⁻¹ band as a result of the exchange was noted.

Figs. 3 and 4 show respectively the effects of heating the exchanged RA2/5 and DA2/5. Surface dehydration is accompanied by a decrease in intensity of the low-frequency component of the vibrational absorption bands for both the exchanged and unexchangeable groups. However, there is an increase in the absorption intensity of the 3,737 cm⁻¹ band, assigned to single hydroxyls, for RA2/5, and in that of the 2,755 cm⁻¹ band, assigned to single deuteriohydroxyls, for DA2/5. These new 'single' absorption bands can now be readily changed, together with some of the low-frequency tail. When samples are heated to higher temperatures, exchange is accompanied by a large degree of chemisorption even with contact times of < 60 sec at room temperature. The spectrum of the D₂O-exchanged RA2/5, after heating to 450°C, was stable after further evacuation for 60 h, showing that the growth of the 3,737 cm⁻¹ band did not result from leakage of the cell.

The spectral results presented show that formation of a silica disk results in a product having certain important differences from the original powder. It is clear that it may be erroneous to make direct comparison between the infra-red results obtained from such pressed disks, and gravimetric and adsorption data determined on the corresponding powders. The evidence suggests that either regions inaccessible to H₂O or D₂O vapour are formed, or that bringing the particles closer together causes enhanced hydrogen bonding which prevents exchange occurring. However, as it is thought that it is the most closely adjacent OH groups which are first lost on dehydration, a fact confirmed by the more rapid decrease in the low-frequency tail of the ν_{OH} band, then such strongly bonded groups would be expected to be more rapidly lost than the exchangeable hydroxyl groups. This is shown not to be the case. Additionally, the increase in the single ν_{OH} (or ν_{OD}), observed on heating, would not be expected by this mechanism. Disks made at lower pressures exhibit the same effects, but to a lesser extent. It is realized that pressures described elsewhere for the preparation of 'Aerosil' disks are sometimes lower; however, 'Aerosil' probably represents an optimum case and other oxides require higher pressures.

HEXAGONAL-MESH STRUCTURES AND STABLE POLYPEPTIDE CHAIN CONFIGURATIONS

By PROF. R. E. DICKERSON

Gates and Crellin Laboratories of Chemistry, California Institute of Technology, Pasadena

HECHTER¹ has recently proposed a hexagonal-sub-unit model for the protein component of cell membranes, based on polypeptide chain structure principles set forth by Warner^{2,3}. However, available experimental and theoretical evidence shows such structures to

be exceedingly unlikely, and the basis for the membrane model therefore should be reconsidered.

Warner has proposed that simple peptide antibiotics such as gramicidin S and actinomycin are built up from a basic hexapeptide unit in which the carbonyl oxygens

Fig. 1. Two resonance forms of the *trans* configuration of the planar peptide bond (I and II) and the *cis* configuration (III)

lie 4.8 Å apart at the corners of a hexagon. The hydrophobic side-chains project from one face of the flat molecule in this model, and the hydrophilic carbonyl and NH groups extend from the other face. Decapeptide antibiotics are then related to the basic hexamer as naphthalene is to benzene, and larger units are built up on a flat hexagonal mesh. The two essential features of the model are the separated hydrophilic and hydrophobic sides, and the regular 4.8 Å hexagonal spacing of carbonyl oxygens on the hydrophilic face, related to the second-neighbour oxygen spacings in the structure of ice. This flat hexagonal mesh model has been extended to the

158-residue protein sub-unit of TMV as well⁴, although the stacking model shown does not agree well with electron micrographs of the TMV molecule.

Hechter's membrane model uses flat spiral hexagonal sub-units of a similar size packed in an overlapping double layer with hydrophobic faces paired between layers, and with channels or pores through the membrane. Several properties of the membrane are then explained with considerable ingenuity from this model. There may well be elements of truth in the cell membrane model, but the peptide hexamer principles on which it is based are energetically untenable.

The fundamental flaw in the peptide model is that it cannot be built with the desired properties without deforming the amide or peptide linkages severely out of their stable planar configurations (Fig. 1). In contrast, there is considerable evidence for the true planarity of peptide bonds in peptides and proteins.

Theoretical Evidence

Early structural work on small compounds by Corey and Pauling^{5,6} and others showed the amide bonds to be uniformly planar. Pauling explained this in terms of the joint contribution of two resonance structures, I and II in Fig. 1. The central C—N bond would be shortened from its normal 1.475 Å as it assumed a partial double-bond character and the C=O distance would increase beyond 1.205 Å as it lost double-bond character. Assuming a 60:40 contribution of I and II, the expected C—N distance was calculated to be 1.32 Å and the expected C=O distance to be 1.24 Å.

The resonance stabilization energy of the amide bond has been calculated by Pauling and Sherman^{7a,b} from

(a) Per cent double-bond character is taken from Hahn (ref. 8), based on both O—N and C=O bond-lengths. Later approximate values are interpolations based on C—N distances only. The limits of error in these figures are wide. The difference in bond-length between complete single-bond character and complete double-bond character is only about 0.24 Å, and an uncertainty (three standard deviations) of 0.08 Å in bond-length would correspond to an uncertainty in per cent double-bond character of ± 12 per cent.

(b) Maximum deviation in Å of any atom from the best least-squares plane fitted to the amide group, or alternatively, angle of twist about the C—N bond in degrees. For small angles of twist, β , it is approximately true that, $\sin \beta = 0.8 d$, where d is the deviation in Å of one of the corner atoms of the amide plane from co-planarity. The greatest observed non-planarity is 0.20 Å or 9°, corresponding to a strain energy of only 0.5 kcal/mole.

(c) Standard deviations in most cases have been obtained from least squares refinement. There is a 95 per cent chance that a variation of as much as three times the standard deviation is not statistically significant. This should be kept in mind when assessing limits of error in the per cent double-bond figure.

(d) The value of only 16 per cent double-bond character obtained from this 1.39 Å bond-length is misleading. The authors themselves state that, because of experimental errors in the data, the difference of 0.07 Å between this value and the expected one of 1.32 Å is not significant (ref. 31).

(e) The second C—N bond is badly distorted in the crystal because of the chelation of all three nitrogens to the same copper atom. Note that the C=O bonds, farther removed from the copper atom, are as expected for about 40 per cent double-bond character. In spite of the considerable lengthening of the second C—N bond this amide is only twisted 7.4° out of planarity.

(f) No standard deviations are given, but single bonds are observed to have a mean variation of 0.08 Å from their expected values.

(g) Cysteinyl glycine sodium iodide has been reported (ref. 11) as having a non-planar amide. The original structure analysis is definitely in error and the data are being re-analysed by Dr. J. Donohue (ref. 12).

(h) For further discussions of amide planarity, see refs. 8, 9 and 10.

thermodynamic heats of formation of formamide, acetamide and oxamide. Values of 21.4, 20.5 and 23.7 kilocalories per mole of amide bonds, respectively, were obtained. In view of the similarity of C=O and C—N bond-lengths in these compounds and in peptides, the resonance energy per amide in a polypeptide chain is unlikely to differ from 21 kcal by more than a few kcal. A reasonable measure of the strain energy involved in twisting an amide linkage out of planarity about its C—N bond by an angle β is then: $E = 21 \sin^2 \beta$ kcal/mole. Hence even a twist of 30° will require a strain energy of more than 5 kcal.

Experimental Evidence

The experimental evidence for the planarity of the peptide bonds falls into three categories: di- and tripeptides and related compounds, fibrous proteins, and globular proteins. The results of careful X-ray analysis of compounds in the first category are given in Table 1. In all cases the amide bond has been found to be planar, and in all the peptides it is in the *trans* configuration (I rather than III in Fig. 1). In all cases the expected shortening of the C—N and lengthening of the C=O bond are found, and the contribution of resonance form II usually lies in the 30–40 per cent range.

These observations are given added significance by the X-ray examination of potassium benzylpenicillin, a larger molecule containing one amide bond³⁴. The bond is *trans* and planar, and showed the expected changes in bond-lengths (Table 1).

In X-ray analyses of fibrous proteins, accurate bond parameters are not sought, and analysis consists essentially in fitting sterically acceptable models to the observed diffraction pattern³⁵. Nevertheless, the field only began to produce results after the work of Corey *et al.* had produced standard parameters for polypeptide chain geometry^{3,6}. In all work since then, whether with α -helices, β -sheets, collagen triple helices or more complex structures, it has never been necessary to invoke non-planar amides to satisfy the diffraction pattern, and in only one case (polyproline I (ref. 36)) have *cis* amides been found.

Complete structure analyses are only beginning to appear for globular proteins, and the only ones at near-atomic resolution (2 Å or better) so far are myoglobin^{37,38} and lysozyme³⁹. Two-angstrom resolution does not permit measurement of accurate atomic parameters, but geometry of the peptide links is clear. In all cases, for both myoglobin⁵¹ and a preliminary examination of lysozyme⁵², only *trans* amides were found, planar within the limits of accuracy of the structure (of the order of $\pm 5^\circ$ for myoglobin). The fact that such restrictions are observed in both a high-helix and a moderately low-helix protein, and in both hydrophobic and hydrophilic regions of the molecules, suggests that violations of planarity in other structures will be difficult to justify.

In summary, there is no evidence from any structure analysis, from simple dipeptides to proteins, that the amide bond ever deviates more than a few degrees from planarity, and in all but two or three small cyclic compounds such as diketopiperazine and cyanuric acid and one fibrous polypeptide only the *trans* configuration has been found.

Hexagonal Peptide Models

In contrast to the foregoing evidence, the hexagonal-unit peptide models proposed by Warner²⁻⁴ require the amide bonds to be deformed out of planarity, in some instances by nearly 90° . Of the eighteen amide bonds in a nonadeca-peptide fragment of ACTH¹, only one appears to be *trans* and planar. Four are planar but *cis*, four are skew but nearer *cis* than *trans*, seven are skew but nearer *trans* than *cis*, and two appear to be at right angles. A rough calculation of strain energy based on Pauling's formula, and assigning

twist angles no more precisely than 0° , 45° , 90° , 135° , and 180° to the categories mentioned here as determined from the photograph, gives a value of about 160 kcal/mole.

As part of an X-ray analysis of actinomycin⁴¹ we have tried building Warner's actinomycin molecule shown in Fig. 6b of ref. 2. The total strain energy in this molecule, based on amide deformations measured from the model and accurate to $\pm 10^\circ$, is 120 kcal/mole. An unstrained configuration with eight planar *trans* and two planar *cis* linkages is possible in a model of the same size and shape as Warner's (Fig. 11, ref. 41). However, the structural advantages of Warner's model are largely lost. Only six of the ten carbonyl oxygens extend out from the 'hydrophilic' face, two extend out from the edges and two more now project from the 'hydrophobic' side. Nothing at all resembling a regular hexagonal array of carbonyl oxygens can be seen. Extensive adjustments of the space-filling models have shown no way to segregate hydrophobic and hydrophilic groups or to re-create the oxygen arrangement without deforming the amides from planarity.

If the planarity of the amide bond is accepted as a fundamental principle, then the larger the structure the more difficult it becomes to retain the specific features of Warner's structures. The basic hexapeptide with *cis* amides (Fig. 2b) has α -carbons so close that the structure is only usable for hexaglycine. The *trans* hexamer (Fig. 2a) does place the carbonyl oxygens 4.8 Å apart in a hexagon and extend the side-chains out the opposite side. However, the NH groups fall on the 'hydrophobic' rather than the 'hydrophilic' side.

The decapeptide built up from two fused hexagons is less tractable. The planar *trans* model is shown in Fig. 3 with a bond sketch in the corner. The two re-entrant angles at positions 1 and 6 pose a problem. The amide linkage considered as a unit does not alter the direction of the polypeptide chain (Fig. 4a), and any bending of

Fig. 2. Hexapeptide models with planar amides, in (a) the *trans* and (b) the *cis* configuration. Side-chains are represented only by single carbon atoms attached to the main chain or α -carbon. Note the steric hindrance between these side-chain carbons in the *cis* form.

Fig. 3. Decapeptide with planar *trans* amide bonds, showing the 'hydrophobic' side. Side-chains are represented only by single (β) carbons. Note the presence of the two carbonyl groups (c) on the 'wrong' side of the molecule.

the chain must be produced at the α -carbons (Fig. 4b, c). At re-entrant angles the C_α must be rotated 180° from the position of Fig. 4b to 4c, bringing the side-chain over to the hydrophilic side, where it collides with the carbonyl oxygen.

At any re-entrant angle, therefore, one must either move the side-chain of one residue to the hydrophilic side or replace the L-amino-acid by a D-form. If the L-form is retained, then the adjacent amide group must be rotated so as to move the carbonyl oxygen to the hydrophobic side to get it out of the way unless the residue involved is glycine. Fig. 5 shows the decapeptide with the carbonyl rotated in this manner to the 'wrong' side, and Fig. 6 shows the steric hindrance between carbonyl and side-chain if this is not done. A brief examination of sequences of decapeptide antibiotics⁴² shows that except for gramicidin S (and actinomycin if it is one decapeptide ring), one does not generally find D-amino-acids or glycines paired across the ring.

Larger structures become increasingly difficult. Three rings of Warner's flat spiral TMV structure (Fig. 1 of ref. 4) were built, and the preceding comments about re-entrant angles were checked. A further extension of model building was not felt to be worth while. No less than 64 of the 158 residues in the TMV structure are involved in re-entrant angles in this model, meaning that almost as many carbonyls and side-chains will project from each side unless many of these re-entrant sites are glycine or D-amino-acids. The known amino-acid sequence of TMV (ref. 43) lends no support to this latter idea.

Energy Requirements for Non-planar Amide Structures

It has recently been suggested^{44,45} that, even though the non-planar amide structures (hereafter referred to as 'strained' structures) were not the lowest energy states for small peptides and antibiotics in solution, these structures might be stabilized by hydrogen bonding and hydrophobic interactions when in contact with enzyme

Fig. 4. Space-filling models of: (a) planar *trans* amide group, (b) and (c) α -carbon with hydrogen (H) and side-chain (R). Note that any change in chain direction must occur at an α -carbon site, as the planar *trans* amide group taken as a unit leaves the chain direction unaltered.

Fig. 5. Decapeptide of Fig. 3, showing the 'hydrophilic' side. Note the presence of two side-chains (β , represented by β -carbon atoms only) on the 'wrong' side, and the fact that there is barely room for them.

Fig. 6. Decapeptide of Figs. 3 and 5, 'hydrophilic' side, with the two displaced carbonyls (c) rotated back to the proper side. Note the severe steric hindrance between these two carbonyls and the neighbouring side-chains (β).

surfaces, cell membranes or even like molecules in the form of dimers. By this argument, two peptide configurations, each inherently unstable when the units are isolated, would become a stable system when the units were locked together through the collective effect of a number of weak forces. This is a perfectly valid concept if it is made quantitative, but dangerous if it is not. Undoubtedly the exact conformation of a polypeptide chain can be strongly influenced by binding to a supporting surface or to a smaller substrate molecule. But it is not difficult to show that neither hydrogen bonding nor hydrophobic interactions are sufficiently strong to compensate for the strain energies encountered in these non-planar amides.

In such a quantitative comparison, it is not enough to compare the amide strain energy with the total energy obtained by hydrogen bonds and hydrophobic interactions, for an unstrained polypeptide configuration can always be found with much the same binding properties if not the same precise configuration (as with the two actinomycin models). One must therefore compare the strained molecule in a given set of circumstances with an unstrained molecule in an equivalent environment.

(1) *Average strain energy per amide bond.* With a fragment of ACTH containing 18 amide bonds, a crude strain energy estimate of 160 kcal was obtained. The actinomycin figure of 120 kcal for ten amides is more accurate. Thus, although there is a maximum possible strain energy of 21 kcal per bond for bonds wrenched to right angles, an estimate of 10 kcal per bond as an average in hexagonal-type structures is certainly safe. If such strained structures are to be stable, some factors must be found which will contribute an average energy of at least 10 kcal per amino-acid residue.

(2) *Stabilization by favourable hydrogen bonding with solvent.* If the same number of hydrogen bonds can be formed with the strained and unstrained structures, then there is no stabilization. But now suppose that a fraction y of the possible bonds in the strained form are impossible in the unstrained form. A simple inversion of a carbonyl or NH group from one face of the molecule to the other is not sufficient, and to be inaccessible the group must be buried. Examination of models suggests that certainly not more than 30 per cent of the possible groups will be so buried.

The enthalpy of formation of a hydrogen bond with water is about -5 kcal. The entropy change is less precise, but it will certainly be negative, making the free energy change greater than -5 kcal (less in absolute magnitude). The exact value does not matter, for the conclusions hold even if one takes the least favourable case and neglects the entropy entirely. In this case, the stabilizing contribution of the extra hydrogen bonds in the strained form will be $\Delta F = -5y$ kcal per mole of

amide bonds, or -1.5 kcal at the most. This is quite insufficient to counteract the free energy change of -10 kcal per bond in going to the strained form.

(3) *Stabilization by pairing of hydrophobic faces.* Pairing of hydrophobic faces is energetically favourable not because of van der Waals interactions between hydrophobic side-chains, which amount to only a few tenths of a kilocalorie, but because of the removal of such groups from the aqueous environment. Kauzmann⁴⁶ has shown that the most important term involved is the entropy one, and has calculated that the removal of one hydrophobic side-chain from water to a non-polar environment is accompanied by a free-energy decrease of no more than about 4 kcal.

Let us assume that in the strained model all hydrogen-bonding and hydrophobic groups are properly segregated to their respective sides of the flat molecule, while in the unstrained version a fraction x of each type is on the wrong side. The free energy of stabilization of the strained molecules by pairing of hydrophobic faces will be $\Delta F_{h,s} = -4$ kcal per amino-acid residue. In the unstrained molecule, only a fraction $(1-x)$ of the hydrophobic groups will be buried, for a stabilization energy of $-4(1-x)$ kcal. But a fraction x of the previously formed hydrogen bonds will be broken because they occurred to groups on the 'hydrophobic' face, producing a destabilization of $+5x$ kcal in the most unfavourable circumstances. The net free energy of stabilization is then $\Delta F_{h,u} = -4 + 9x$ kcal per mole. The lowest reasonable value of x is 0.5, that for a random distribution of types of groups between faces.

The net free energy change in going from unstrained to strained molecules, both with the maximum possible use of hydrophobic interactions, is then:

$$\Delta F = \Delta F_{\text{strain}} + \Delta F_{h,s} - \Delta F_{h,u} = (+10 - 4 + 4 - 9x) \text{ kcal per bond.}$$

If the worst possible case is assumed, comparing a completely ordered strained molecule with an unstrained molecule having random occurrence of side-chains on either side, then $x = 0.5$ and $\Delta F = +5.5$ kcal.

The conclusion is therefore that even if the most favourable hydrogen bonding and hydrophobic interactions are used, the flat, hexagonal-mesh, non-planar-amide structures are unstable relative to a planar-amide form by 5–10 kcal per amide bond.

Summary

The hexagonal-mesh models proposed by Warner, if made with planar amides, do not create distinct hydrophobic and hydrophilic sides and do not place the carbonyl oxygens at the corners of a hexagonal mesh 4.8 \AA on a side as proposed. Moreover, the strain involved in twisting the amides out of planarity is so great that even the best hydrogen bonding and hydrophobic bonding cannot make these strained structures stable. If models of this general type are proposed, they should be based on planar (and probably *trans*) amide groups, and tested with space-filling models rather than hexagonal-mesh diagrams, for that which is true for single or double rings is not necessarily extendable to a semi-infinite mesh.

It is probably reasonable to say that any peptide model with non-planar amides can be regarded from the outset as extremely improbable. But if it proves useful for certain purposes to hypothesize models of this type, then their instability must be kept clearly in mind, and at some point a quantitative numerical justification for such a distorted structure must be made. At present there is no direct evidence for the hexagonal-mesh structures considered here and overwhelming evidence against them.

A NEW INHERITED COAGULATION DISORDER CAUSED BY AN ABNORMAL FIBRINOGEN ('FIBRINOGEN BALTIMORE')

By DR. EUGENE A. BECK, PATRICIA CHARACHE and PROF. DUDLEY P. JACKSON

Department of Medicine, The Johns Hopkins University School of Medicine and Hospital, Baltimore, Maryland

An inherited abnormality of fibrinogen resulting in an asymptomatic clotting defect was described by Ménaché¹. Another congenital qualitative defect of fibrinogen associated with a symptomatic coagulation

disorder has been discovered in a 29-year-old woman of Anglo-Saxon origin². The patient was admitted to the Johns Hopkins Hospital because of femoral vein thrombosis following minor trauma. She had a history of a

Table 1. COAGULATION STUDIES

	Patient %	Normal control %
Fibrinogen assays:		
(a) Thrombin clotting time (ref. 3).	35 mg	175 mg
(b) Tyrosine determination (ref. 4)	104 mg	180 mg
(c) Immunodiffusion (ref. 5)	180 mg	180 mg
Prothrombin time (one-stage)	45	60-100
Prothrombin time after addition of normal fibrinogen	80	
Specific assays for factors II, V, VIII, IX, XIII	Normal	
Euglobulin lysis time	Normal	
Platelet count	224,000-284,000	
Platelet function (aggregation and clot retraction)	Normal	

mild haemorrhagic diathesis characterized by frequent bruising, epistaxis and menorrhagia, and a history of a previous severe thrombotic episode of several months' duration.

On preliminary investigation a friable whole blood clot was noted. Assays of fibrinogen (Table 1) indicated the presence of a poorly clottable fibrinogen in the patient's plasma: subnormal values were obtained by a method that depends on the rate of clotting in the presence of standard amounts of thrombin³ whereas the amount of immunologically detectable fibrinogen was within normal limits. Further studies of coagulation demonstrated that fibrinogen alone was responsible for the clotting disorder. An abnormally prolonged prothrombin time was corrected by the addition of normal fibrinogen to the patient's plasma. Fibrinolytic activity as measured by euglobulin lysis was not increased. Recalcified plasma clots were insoluble in urea, indicating that factor XIII (fibrin-stabilizing factor) activity was present.

The rate of clotting of the patient's plasma by thrombin¹ (Thrombin Topical, Parke, Davis and Company, Detroit, Michigan) was retarded, especially at low concentrations of thrombin (Fig. 1). Addition of calcium chloride (0.025 M) partially corrected the prolonged thrombin clotting time of the patient's plasma but had little effect on the thrombin clotting time of normal plasma.

The rate of clotting of normal plasma or fibrinogen by thrombin was not inhibited by the patient's plasma or by her fibrinogen. In contrast to acquired defibrination syndromes due to intravascular coagulation, the clotting defect was not corrected by therapy with heparin and infused normal fibrinogen had a normal survival time in the patient's circulation.

The venom of *Bothrops jararaca* ('Reptilase', Pentafarm, Basle, Switzerland), which is known to clot fibrinogen by splitting off predominantly peptide A (ref. 6), did not clot the patient's prothrombin-free plasma. On addition of 'Reptilase' and calcium ions a clot formed, but at a comparatively slow rate (Table 2).

The thromboelastogram (prepared by Dr. S. Attar, University of Maryland, Baltimore, Maryland) showed an abnormally small maximal amplitude (Fig. 2). The rate of clot lysis was not increased. In the absence of platelet abnormalities an abnormal structure of the final clot was therefore suggested.

The patient's fibrinogen could not be distinguished from normal fibrinogen on paper electrophoresis and so far consistent differences of migration have not been observed on starch-gel electrophoresis. On immunodiffusion using rabbit antibody prepared against normal human fibrinogen, the precipitation lines that formed in the presence of normal and patient plasma fused without observable spurring (Fig. 3). However, on immunoelectrophoresis minor but reproducible migration differences were found. The abnormal fibrinogen, therefore, appeared to be

immunochemically similar to, but not identical with normal fibrinogen.

These experiments indicated that the defect represented a dysfibrinogenaemia rather than hypofibrinogenaemia and suggested that the disorder might be inherited. Investigation revealed the presence of a similar abnormal fibrinogen in all three daughters of the probanda, whereas the two sons had normally clottable fibrinogen. Two of the daughters had a history of a significant bleeding tendency. The disorder appears to be transmitted by dominant gene (Fig. 4). No further abnormal family members were found in three generations of the patient's mother's family. The father's family was not available for investigation.

Qualitative abnormalities of fibrinogen may be overlooked, particularly if the defect does not produce symptoms. The defect described by Ménaché¹ was discovered in a patient with no haemorrhagic symptoms. In our probanda and in two of her children an abnormal bleeding tendency is clearly present. It remains to be shown

Fig. 1. Thrombin clotting times using serial dilutions of bovine thrombin were performed on normal and patient citrated plasma. Thrombin was diluted with barbital buffer (pH 7.35) alone or with 50 vol. per cent 0.050 M CaCl_2 and barbital buffer. \circ , Normal + thrombin + buffer; \bullet , normal + thrombin + calcium; \triangle , patient + thrombin + buffer; \blacktriangle , patient + thrombin + calcium.

Fig. 2. Thromboelastogram on re-calcified platelet-rich citrated plasma. Maximal amplitude: normal, 34.0 mm; patient, 4.5 mm.

Fig. 3. Immunodiffusion studies. Centre well: antibody against normal fibrinogen. Peripheral wells: citrated plasma, undiluted. Normal plasma and patient plasma are in alternate wells. Complete fusion, shown by a smooth ring, is present indicating antigenic identity in this system.

Table 2. CLOTTING TIME OF PROTHROMBIN-FREE CITRATE PLASMA BY 'REPTILASE'

whether the thrombotic episodes are related to the defective fibrinogen.

The exact sites of the structural defects in the abnormal fibrinogens described by Ménaché and by us are not known. In contrast to the fibrinogen described here, the abnormal fibrinogen described by Ménaché interfered with the conversion of normal fibrinogen by thrombin, suggesting that the two abnormal proteins may be dissimilar. It has been shown that the amino-acid sequence of the peptides which are split off from fibrinogen by thrombin affects the interaction between thrombin and fibrinogen⁷. The absence of clot formation of our patient's fibrinogen in the presence of 'Reptilase' suggests a possible abnormality of peptide A. The effect of calcium ions in partially correcting the clotting defect cannot be explained on the basis of our present knowledge.

The abnormal fibrinogen described here is, so far, characterized as follows: (1) it clots at an abnormally low rate in the presence of thrombin; (2) in the absence

of calcium ions it does not clot on addition of 'Reptilase'; (3) calcium partially corrects the defect in the presence of both thrombin and 'Reptilase'; (4) the structure of the final clot is abnormal, but the transamidation mechanism induced by factor XIII appears not to be involved; (5) the abnormal fibrinogen does not interfere with clotting of normal fibrinogen; (6) it can be distinguished from normal fibrinogen by differences in migration on immunoelectrophoresis; (7) its presence is controlled by an abnormal dominant gene and leads to a mild haemorrhagic disorder.

As a consequence of the rapidly increasing knowledge concerning the structure of fibrinogen and the fibrinopeptides it can be assumed that further structural abnormalities may be found in the future. Some of the cases which have been thought to have a dominantly inherited hypofibrinogenaemia⁸ may in fact be found to have a dysfibrinogenaemia. A suggested nomenclature to distinguish molecular changes of a protein is that in use for the characterization of abnormal haemoglobins. Accordingly, we would like to designate the fibrinogen described here as 'fibrinogen Baltimore'.

This investigation was supported in part by a contract with the U.S. Atomic Energy Commission and grants from the National Institutes of Health of the U.S. Public Health Service.

MECHANISM OF INTESTINAL ABSORPTION: TRANSPORT OF METHIONINE AND SODIUM BUTYRATE BY INTRACELLULAR PLASMA

By S. L. HART and DR J. A. NISSIM

Pharmacology Department, Guy's Hospital Medical School, London, S.E.1

A THEORY of the mechanism of intestinal absorption involving active transport by a spectrum of mobile intracellular proteins was put forward in a previous article¹. This resulted from the analysis of the effects of cetrime and other protein-binding substances, such as chloroquine and thevetin, on the intestinal absorption of glucose in the mouse during intraluminal perfusion of the small intestine. The main points of the theory are: (a) phloridzin acts on a first receptor, blocking a portal of entry for sugars and short-chain fatty acids in the cell membrane; (b) phloridzin is attached to a protein moiety of the first receptor, since phloridzin itself can be displaced, and thus inactivated, by high concentrations of cetrime²; (c) cetrime acts on a second, mobile, receptor, which is the one concerned in active transport. Its inhibition results in leakage of blood glucose to the intestinal lumen; (d) stimulation and inhibition of absorption can be produced by small and large concentrations, respectively, of substances competing with the nutrient for this second receptor; (e) the second receptor is located on intracellular mobile proteins which are characterized by a spectrum of affinities for nutrients and drugs; (f) the association-dissociation constants for proteins, drugs and nutrients are controlled by a pH or electrochemical gradient, which is maintained by the metabolic activities of the cell and requiring the expenditure of energy.

The localization of the second receptor within the cell membrane was considered, but was rejected as unlikely for two reasons. Effective potentiation of phloridzin by cetrime, which removes the former from silent receptors, took half an hour to become established. The phloridzin receptor could not, therefore, be on the surface of the cell

membrane, for potentiation would have been immediate. Furthermore, the second receptor must lie more deeply still from the surface of the cell, and it seemed inconceivable to accommodate a whole spectrum of mobile proteins and their gradient-establishing enzymes, in addition to the distinct protein of the first receptor, within the 75-Å wide cell membrane, of which some 40 Å consists of a lipid outer and inner layer.

The general applicability of the theory was next investigated. It was decided to seek parallel evidence for other species and nutrients. The effect of the cationic cetrime and the anionic sodium lauryl sulphate (B.P.) on the absorption of the amino-acid methionine, the short-chain fatty acid compound sodium butyrate, and glucose, was therefore studied in albino rats. Appreciable inhibition of the absorption of the three nutrients had been demonstrated previously in this species¹, as well as the potentiation of the phloridzin effect on glucose absorption by cetrime. The important problem of stimulation of absorption by low concentrations of different protein-binding inhibitor drugs had not been investigated in the rat. Stimulation was important, because it indicated mobility of the second receptor^{3,4}, while its poorly specific interaction with protein-binding drugs indicated its intracellular localization on the mobile proteins.

The drugs were dissolved in 0.9 per cent sodium chloride containing 0.2 per cent (w/v) D-glucose, DL-methionine and sodium butyrate. 50 ml. of solution was perfused through the lumen of the proximal 60 cm of the small intestine for 0.5 h. The percentage absorption of each nutrient was calculated from estimations of their final concentrations. The methods used in the estimations

Table 1. EFFECT OF CETRIMIDE ON THE PERCENTAGE INTESTINAL ABSORPTION (MEAN \pm S.E.) OF GLUCOSE, BUTYRATE AND METHIONINE IN THE RAT
No. of experiments in parentheses

were essentially as before¹, but a slight modification of the methionine estimation requires the reduction of previously published values by a factor of 1.4, before they can be compared with the present values.

The results obtained at six concentrations of cetrimide are shown in Table 1. At a concentration of 10⁻³, significant inhibition of absorption of all three nutrients occurred, although the inhibition was smaller in each case than that obtained with previous samples of cetrimide^{1,2}. At lower concentrations, there was definite stimulation of absorption, which was maximal at 2.5 \times 10⁻⁵ for glucose, 5.0 \times 10⁻⁶ for butyrate, and 10⁻⁵ for methionine. At lower concentrations still, absorption returned to its level in control animals.

Sodium lauryl sulphate had only a moderate inhibitory effect on the absorption of glucose compared with that of cetrimide. The results obtained with ten concentrations of sodium lauryl sulphate are given in Table 2. Maximal stimulation of glucose absorption occurred at 5.0 \times 10⁻⁶, although there was also some stimulation at 5.0 \times 10⁻⁵ and 2.5 \times 10⁻⁵. Marked stimulation of butyrate absorption was observed with sodium lauryl sulphate at 10⁻⁴, 2.5 \times 10⁻⁵, and combination of the four *P* values from the individual *t*-tests in this region gave *P* < 0.0005. Stimulation of methionine absorption occurred between 5.0 \times 10⁻⁵ and 5.0 \times 10⁻⁶, although not at the intermediate concentration of 10⁻⁵, which gave a value no different from that of the control.

Although the stimulation of absorption obtained with these two drugs was not as marked as the stimulation of glucose absorption in the mouse, the low *P* values fully establish the stimulating effect at low concentrations for all three nutrients. These results assume greater significance when considered alongside the parallel results in the mouse, since they constitute further confirmatory evidence for the proposed theory of the mechanism of intestinal absorption. The observation that both a cationic and an anionic compound, known to bind protein in an unspecific reaction, stimulate the absorption of the three nutrients at different concentrations, lends strong support to the concept that active transport involves the intracellular proteins which have different affinities for individual nutrients and drugs. It is possible that different nutrients bind to different proteins, but they may also bind to different sites on the same protein.

Inspection of the concentrations at which stimulation occurred with cetrimide shows that for all three nutrients there was a single peak, though the range at which butyrate absorption was stimulated was rather wide. By contrast, stimulation with sodium lauryl sulphate occurred

at more than one peak for glucose and methionine, and the range of concentrations for butyrate stimulation was much wider. Both peak multiplicity and range width suggest that more than one protein carrier might be involved, the carriers exhibiting particularly different affinities for sodium lauryl sulphate, but the presence of impurities cannot be excluded.

The first receptor in intestinal sugar transport was previously studied in some detail in the mouse and rat^{1,2}. It was concluded that stimulation of sugar absorption in the mouse was due to the action of small doses of a competitive substrate (or inhibitor) on the second, not the first, receptor. This must also be true in the rat, for the results of experiments in the two species are similar. As for sodium butyrate and methionine little is known about their entry mechanisms. The partial block to butyrate absorption by phloridzin^{1,2} may be exerted on one of the entry mechanisms, for butyrate might enter partly through a pore and partly through the lipid of the cell membrane. For amino-acids, entry through the lipid part of the cell membrane has been suggested⁶, and a two-stage system of absorption has been proposed⁷, involving entry and subsequent active transport. The evidence presented here strongly suggests that for all three nutrients stimulation and inhibition of absorption, by low and high concentrations of cetrimide and sodium lauryl sulphate, occur by competition at the second receptor, concerned with active transport. We shall therefore confine our discussion to the various possible modes of stimulation that may be produced by an inhibitor of the second receptor. Since the simple model of carrier transport capable of achieving this was proposed by Wilbrandt and Rosenberg^{3,4}, other possible mechanisms have been suggested or demonstrated. These different stimulation-inhibition models will therefore be considered to see which of them would be applicable to our findings.

The first is the mobile carrier transport model of Wilbrandt and Rosenberg. According to this, stimulation or inhibition depends on whether the factor ($I' + 1 - S_1/S_2$) in their formula is negative or positive. Here S_1 and S_2 represent substrate or nutrient concentration at the two ends of the carrier path, and I' is the equilibrium value of the inhibitor substance, all three being divided by the respective equilibrium association-dissociation constant for substance and carrier. This is the model adopted previously in the new theory for the mechanism of intestinal absorption.

The second hypothesis is that of an exchange reaction at a membrane surface in a model of carrier transport

ving a 1:1 nutrient-carrier stoichiometry (Jacquez^{6,8}, ong⁹, Guroff⁸, Christensen *et al.*⁹). If *C* indicates carrier, ternary combination *CSI* with subsequent breakdown *CS* + *I* leads to more rapid formation of *CS* than by ect combination. Employing a more comprehensive rome for his models, Jacquez obtained equations for ich simple analytic solutions could not be found. nsideration of idealized stationary states, however, d him to the conclusion that the simple 1:1 nutrient- rrier stoichiometry of Wilbrandt and Rosenberg could t produce stimulation at any concentration of the ibitor, when the value of *S*₂, the concentration of the bstrate at the inner end of the transport system, remains ro. The same result is obtained by putting zero for in the Wilbrandt-Rosenberg formula. This state of airs may conceivably apply for certain cells, such as e Ehrlich ascites cells, if the rate of utilization of *S* by e cell is more rapid than its absorption, but it scarcely plies to the intestinal absorption of nutrients. Further- ore, it seems unlikely that there is ternary complex rmation allowing exchange reaction in the case of all ee nutrients of the present investigation.

Thirdly, a model of carrier-transport having a 2:1 rrient-carrier stoichiometry was proposed by Jacquez⁶. his allows the formation of *CSS*, *CSI* and *CII* at the same ne. The derived equations again permit early stimula- on and subsequent inhibition. While this may be the se for some nutrients, it would seem unlikely to represent e standard form for the general carrier-transport action.

Fourthly, in a model of polymer enzyme splitting into idividual units by low concentrations of the inhibitor bstance, Gerhart and Pardee¹⁰ have explained the tivation and inhibition of aspartic transcarbamylase by aleate on the hypothesis that the enzyme was composed f four units, forming a tetramer, and that low concentra- ons of maleate broke the tetramer, enabling the aspartate o become bound to the enzyme units. At higher concentra- ns, the maleate not only broke the tetramer, but so competed with the aspartate for the enzyme sites, thus ctng as an inhibitor. Such a system shows a sigmoidal ose-response curve, while the single enzyme or carrier- ransport units, which follow Michaelis-Menten kinetics, ow a hyperbolic type of curve. Michaelis-Menten

kinetics have been shown to hold for the intestinal absorption of most nutrients of the type studied here¹¹⁻¹³. That the polymer type of system is general, and would thus apply to all three nutrients, again seems unlikely.

The fifth model involves the facilitation of transfer by increase of oppositely charged groups along pore or path of entry. Rummel and Stupp¹⁴ found that mersalyl stimulated intestinal calcium transport at 5.0×10^{-4} M and inhibited it at 5.0×10^{-3} M. They postulated that mersalyl molecules were bound in charged pores, and the increase in anionic groups, thus produced, stimulated calcium transfer. This may evidently be important for ionized particles, but unlikely to constitute a general mechanism of the type observed in this investigation.

In conclusion, analysis of the results reveals the stimula- tion-inhibition transport pattern to be general in its applicability to species and nutrients. Among the five different possible models, that described by Wilbrandt and Rosenberg is the simplest, and seems the only one that could fit all the results and qualify for a general carrier-transport system with interactions that are not highly specific. The present investigation, therefore, gives a more general significance to the mechanism of intestinal absorption proposed previously, which attributes active transport to a spectrum of intracellular carrier proteins in the cell plasma.

STOICHIOMETRY OF PROTON TRANSLOCATION THROUGH THE RESPIRATORY CHAIN AND ADENOSINE TRIPHOSPHATASE SYSTEMS OF RAT LIVER MITOCHONDRIA

By DR PETER MITCHELL and DR. JENNIFER MCYLE

Glynn Research Laboratories, Bodmin, Cornwall

ACCORDING to the chemiosmotic hypothesis of oxidative and photosynthetic phosphorylation proposed by Mitchell¹⁻⁴, the linkage between electron transport and phosphorylation occurs not because of hypothetical energy-rich chemical intermediaries as in the orthodox view, but because oxido-reduction and adenosine triphosphate (ATP) hydrolysis are each separately associated with the net translocation of a certain number of electrons in one direction and the net translocation of the same number of hydrogen atoms in the opposite direction across a relatively ion-, acid- and base-impermeable coupling membrane (see also ref. 5). Thus, the chemiosmotic hypothesis, unlike the orthodox chemical hypothesis, predicts that oxido-reduction through the respiratory chain of the mitochondrial membrane system, and ATP hydrolysis through the membrane-located ATPase, should each be accompanied by the stoichiometric translocation of protons (written $\rightarrow H^+$) across the coupling membrane; and that the P/O

quotients observed during respiratory chain phosphorylation should be the product of the $P/\rightarrow H^+$ quotient of the ATPase system and the $\rightarrow H^+/O$ quotient for oxidation of the substrate through the respiratory chain system. It was thought that the direct measurement of $P/\rightarrow H^+$ and $\rightarrow H^+/O$ quotients in rat liver mitochondria would afford a means of testing the chemiosmotic hypothesis, and the present article gives a preliminary report of the results of this quantitative test.

Two main conditions must be satisfied for the accurate measurement of $P/\rightarrow H^+$ and $\rightarrow H^+/O$ quotients: (i) the $\rightarrow H^+$ measured must correspond to a known amount of ATP hydrolysed or of oxygen consumed; (ii) the measurements of $\rightarrow H^+$ must be done in such a way as to minimize the unknown extent of back flow or exchange of H^+ ions and OH^- ions across the membrane system during ATP hydrolysis or substrate oxidation. Estimates of the stoichiometry of H^+ 'secretion' accompanying divalent cation uptake^{6,7} or during monovalent cation uptake in presence

of valinomycin or gramicidin^{8,9} in steadily respiring or ATP-hydrolysing mitochondria are qualitatively interesting, but cannot be relied on quantitatively because they do not satisfy the foregoing conditions. We have met condition (i) by adding a known small quantity of ATP or oxygen to a lightly buffered anaerobic mitochondrial suspension and recording the consequent change of pH (ΔpH) in the suspension medium with a glass electrode during virtually complete hydrolysis of ATP to ADP and P_i , or virtually complete reduction of the added oxygen by substrate present in the suspension medium. Condition (ii) was fulfilled by using quantities of ATP or oxygen such that the electrochemical potential gradient of H^+ ion developed across the mitochondrial membrane system during the transient ATPase or electron transport reaction was sufficiently small and brief to permit ΔpH recordings to be made before much back flow of H^+ or OH^- ions had occurred.

The buffering capacity of the system that we have used was almost independent of pH within a given range of 0.1 pH unit, and readings of virtually instantaneous pH change within the given range were proportional to the amount of H^+ ion (ΔH^+) effectively added to or removed from the phase in acid-base equilibrium with the mitochondrial suspension medium (henceforth called the 'outer phase'). It was thus possible, by suitable calibrations of ΔpH versus ΔH^+ with standard acid or base, to compute ΔH^+ values from the observed respiration-driven and ATPase-driven ΔpH values. As we shall show later, there are sound reasons for concluding that the ΔH^+ values obtained in this way represent the protons translocated ($\rightarrow H^+$) across the mitochondrial coupling membrane that separates an inner mitochondrial phase (probably the interior of the cristae) from the outer phase.

For the measurements of $\Delta H^+/O$, the mitochondria were liberated from male Wistar rat livers by homogenization in ice-cold 0.25 M sucrose, and the mitochondria were largely freed of cell debris, microsomes, and 'fluffy layer' by conventional differential centrifugation in 0.25 M sucrose at 4°C. For the measurements of $P/\Delta H^+$, the mitochondria were prepared by a similar procedure, except that a solution containing 0.21 M sucrose, 1 mM potassium chloride, and 10 mM sodium ethylenediamine tetraacetate (EDTA) was substituted for 0.25 M sucrose in order to reduce the concentration of free Mg^{++} . The stock mitochondrial suspensions (60 mg protein/ml.) were stored briefly in 0.25 M sucrose under semi-anaerobic conditions at 4°C before use.

The ΔH^+ measurements were done in a thermostatically controlled cylindrical glass cell of 6 ml. capacity containing an H^+ -sensitive glass electrode, a saturated potassium chloride junction leading to a calomel half-cell, a Clark oxygen electrode, and a magnetically driven glass impeller giving vigorous stirring. The cell could be closed by a glass piston, but a shallow groove in the piston, parallel to the axis of the cell, permitted the insertion of a fine glass needle so that nitrogen could be bubbled in to flush oxygen from the cell, and reagents could be added from calibrated micro syringes. Oxygen from the air was excluded by a jet of nitrogen continuously directed at the top of the piston. The normal procedure was to flush the oxygen from the suspension medium with oxygen-free nitrogen while the glass piston was at the top of the cell. The cold mitochondrial suspension (0.6 ml.) was then introduced to give a total volume of 6 ml., the piston was lowered on to the surface of the suspension, and 20 min was allowed for temperature and ionic equilibration before commencement of ΔpH measurements. The H^+ -sensitive glass electrode and the potassium chloride junction/calomel half-cell reference system were connected through conventional valve-potentiometer circuitry, the output of which drove a strip-chart recorder giving a full-scale deflexion corresponding to 0.10 pH unit. The measurements were routinely made between pH 7.0 and 7.2 at 25°C in a medium containing 25 mM sucrose, 150 mM potassium

chloride, and 3.3 mM glycyl-glycine-potassium hydroxide buffer, and any variations of these conditions or additions to or changes in this 'normal medium' are referred to the text. The system generally exhibited a small constant rate of pH drift after equilibration, and the time course of ΔpH was corrected for the drift by plotting from a baseline having the slope of the pH drift. Oxygen was added as air-saturated or oxygen-saturated carbon-dioxide-free 0.15 M potassium chloride from a micro-syringe (injection time < 1 sec), and the amounts of oxygen were computed from the relevant temperature-solubility tables for pure water¹⁰, corrected by a factor of 0.9 for the effect of ionic strength¹¹. Mitochondrial protein was estimated by the method of Itzhaki and Gill¹².

Electron transport system. Fig. 1a shows a typical time course of ΔpH and ΔH^+ resulting from the oxidation of β -hydroxybutyrate at 25°C. There was a rapid acidification of the suspension medium, beginning immediately after the addition of oxygen, and a slower, approximate exponential decay of ΔpH to zero. The value of ΔH^+ , corresponding to the peak of the curve of Fig. 1a is 5.4. The controlled and uncontrolled rates of oxygen reduction by the mitochondria under these conditions were found to be respectively 10 and 25 μg atom O/g protein min, and thus it can be estimated that in the experiment of Fig. 1 the oxygen would be consumed within 5 sec. The ΔH^+ quotient for the experiment of Fig. 1a was accordingly corrected for ΔpH decay by a small (linear) extrapolation to time 5 sec, giving a value of 5.96. Sixteen measurements of the corrected $\Delta H^+/O$ quotient on four different batches of mitochondria have yielded a mean value 5.90 ± 0.33 . When the amount of oxygen injected in the 6-ml. mitochondrial suspension is varied between 1 and 5 μg atom O there is little effect on the appropriately corrected $\Delta H^+/O$ quotient, but for larger amounts of oxygen the $\Delta H^+/O$ quotient falls to relatively low values, becoming zero in the steady state. Similar measurements on the $\Delta H^+/O$ quotient for oxidation of 2 mM succinate at 25°C in presence of 0.4 μM rotenone (to stop NAD-linked oxidations) have given a mean corrected value of 3.25 ± 0.08 . However, as shown in the typical pair of experiments described by Fig. 1, succinate causes an enhanced ΔpH decay rate (probably due to specific succinate/ OH^- antiport), which can be largely suppressed at 5°C. Our measurements of the corrected $\Delta H^+/O$ quotient for succinate oxidation at 5°C give a mean value of 4.07 ± 0.11 . Unlike the value for succinate oxidation there is no increase in the $\Delta H^+/O$ quotient for β -hydroxybutyrate oxidation on lowering the temperature from 25°C to 5°C, and this is consistent with the fact that the rate of ΔpH decay is not appreciably temperature dependent in the presence of β -hydroxybutyrate.

The $\Delta H^+/O$ quotient for succinate oxidation at 5°C depressed towards zero as the amount of oxygen increased, just as in the case of β -hydroxybutyrate oxidation.

Fig. 1 Time course of ΔpH and ΔH^+ during oxidation of β -hydroxybutyrate at 25°C. Oxygen (23.5 μg atom in 50 μl . 0.15 M potassium chloride) injected into 6 ml anaerobic mitochondrial suspension in 'normal medium' containing 2 mM β -hydroxybutyrate at vertical arrows. Curve a, no addition; curve b, plus 5×10^{-6} M 2, 4-dinitrophenol, curve c, plus 'Triton X-100' (1 mg/ml.)

Fig. 2. Time course of $\Delta H^+/O$ during oxidation of succinate at 25°C and at 5°C. Oxygen (23.5 μg atom in 50 μl . 0.15 M potassium chloride) injected into 6 ml anaerobic mitochondrial suspension in 'normal medium' containing 2 mM succinate plus 0.4 μM rotenone at vertical arrows.

n. The presence of 6 μg oligomycin per ml. mitochondrial suspension enhanced the $\Delta H^+/O$ values for both hydroxybutyrate and succinate by 0.8 per cent in ferent experiments. Our results suggest that, ideally, $\Delta H^+/O$ quotients for succinate and β -hydroxybutyrate oxidation are respectively 4 and 6.

We have interpreted the observed acidification of the suspension medium in the experiments described here as a consequence of a stoichiometric net translocation of protons through the mitochondrial coupling membrane. In order, however, to justify this interpretation, we must include the possibility that the observed $\Delta H^+/O$ values might be due to the stoichiometric accumulation of an anhydride¹³ (for example, $X \sim I$) the synthesis of which would involve the net dissociation of $2H^+$ ions per \sim bond. Fig. 1b shows that when 5×10^{-5} M 2:4-dinitrophenol is present, in an experiment otherwise identical to that of Fig. 1a, there is a much faster ΔpH decay, and the height of the ΔH^+ peak is reduced. Similarly, as shown in Fig. 1c, Triton X-100 (1 mg/ml.) in place of dinitrophenol, virtually abolishes ΔpH and ΔH^+ . Other uncoupling and membrane-lytic agents have been found to behave similarly to DNP and Triton X-100 respectively in this type of experiment. These observations suggest that the respiration-driven pH displacement and its subsequent decay are due to the effective translocation of H^+ or OH^- across the coupling membrane and their subsequent equilibration by diffusion or exchange through the membrane, for dinitrophenol and other uncouplers are known to catalyse the equilibration of H^+ ions across the mitochondrial membrane system^{3,14} and the membrane-lytic agents permit general ionic equilibration between the phases originally separated by the membrane. However, these observations do not completely eliminate the aforementioned possibility that the respiration-driven pH displacement and its subsequent decay might be due to the formation of an $X \sim I$ anhydride in a lipid phase, the subsequent hydrolysis of $X \sim I$ being catalysed by uncouplers and by the detergent membrane-lytic reagents. A different experimental approach is required to shed more light on this question.

Fig. 3 shows a group of four observations under conditions identical to those of Fig. 1a, except that in all but the control (A) stoichiometric amounts of potassium hydroxide were present in the air-saturated saline injected into the mitochondrial suspension. We have observed in a number of such experiments that, after the respiration-driven pH displacement: (i) the rapid pH shift caused by the potassium hydroxide present in the saline is proportional to the amount of potassium hydroxide added and is not evidently enhanced or decreased by any chemical reaction consequent on changing the pH with the potassium hydroxide solution; (ii) the subsequent change of the pH of the outer medium with time can be either positive or negative, depending on the outer pH , within a total range of only 0.15 pH unit; (iii) there is one particular

pH at which the outer medium will remain constant after the respiration-driven pH displacement.

If the initial respiration-driven acidification of the outer medium were due to the formation of an $X \sim I$ anhydride, and the subsequent hydrolysis of $X \sim I$ were responsible for the ΔpH decay, it is difficult to account for the fact that the upward pH movement corresponding to the ΔpH decay is eliminated by raising the outer pH by only 0.1 unit relative to the initial pH , and that it is actually reversed by raising the outer pH by 0.2 unit—especially as the normal $\Delta H^+/O$ values have been found in other experiments to be almost independent of pH between pH 6 and 8. On the other hand, if there is no net production or consumption of H^+ ions during the respiration-driven pH displacement, but simply an effective displacement of H^+ ions outwards (or OH^- inwards) across the coupling membrane, the fall in the external pH ($-\Delta pH_o$) should be accompanied by a rise in the internal pH (ΔpH_i), and the magnitudes of ΔpH_i and $-\Delta pH_o$ should be in the inverse ratio of the buffering powers ($\Delta H^+/\Delta pH$) of the respective phases. Further, the ΔpH_o decay, being due to the inward diffusion or exchange of H^+ ions (or outward diffusion or exchange of OH^- ions), should depend on the pH differential across the membrane, and the ΔpH_o decay should therefore be arrested or reversed by raising the external pH (pH_o) appropriately. Assuming that the pH differential across the membrane ($pH_i - pH_o$, or $pH_i + \Delta pH_i - \{pH_o + \Delta pH_o\}$) tends to decay to zero or to some constant value, the internal respiration-driven pH displacement will be given by the total shift of the outer pH required to result in a stable outer pH value after the respiration-driven H^+ displacement. It will be seen from Fig. 3 that the respiration-driven ΔpH_o is 0.0120 unit, giving a corrected value of 0.0135 unit, and that ΔpH_i , equated with the total ΔpH_o required to give a stable pH after the respiration-driven H^+ displacement, is approximately 0.11 pH unit. The ratio $\Delta pH_i/\Delta pH_o$ due to the respiration-driven H^+ displacement is thus about 8. It has been possible to estimate the buffering powers of the inner and outer phases over the appropriate pH range by titrating mitochondrial suspensions with standard hydrochloric acid or potassium hydroxide, (a) adding aliquots of acid or alkali quickly and extrapolating the titre to zero time, giving the buffering power of the outer phase ($\Delta H^+/\Delta pH_o$); (b) titrating in presence of reagents catalysing equilibration of H^+ across the membrane (for example, 5×10^{-5} M DNP + 200 μg

Fig. 3. Effect of injection (at vertical arrows) of 25 μl . 0.15 M potassium chloride containing oxygen (1.8 μg atom) and different amounts of potassium hydroxide on the pH of an anaerobic mitochondrial suspension in the presence of β -hydroxybutyrate at 25°C. A, No potassium hydroxide; B, plus 475 μM equiv. potassium hydroxide; C, plus 665 μM equiv. potassium hydroxide; D, plus 855 μM equiv. potassium hydroxide. External buffering power of the mitochondrial suspension across pH 7.15 in this experiment is 5.7 $\mu\text{equiv.}/pH$ unit.

'Triton X-100' per ml.) to obtain the sum of inner and outer buffering powers ($\Delta H^+/\Delta p\text{H}_o + \Delta H^+/\Delta p\text{H}_i$). The buffering power of the inner phase ($\Delta H^+/\Delta p\text{H}_i$) is given by difference. For the mitochondria used in these experiments in the 'normal medium' the approximate values of $\Delta H^+/\Delta p\text{H}_i$ and $\Delta H^+/\Delta p\text{H}_o$ are 130 and 950 $\mu\text{equiv. H}^+/\text{pH unit ml. mitochondrial suspension (containing 6 mg protein/ml.)}$ respectively across $\text{pH } 7.15$, giving a buffering power ratio of 7.3. This agrees satisfactorily with the $\Delta p\text{H}_i/\Delta p\text{H}_o$ of 8 estimated above.

There appear from the foregoing experiments to be rather convincing grounds, both qualitative and quantitative, for concluding that the respiration-driven pH changes described in this article are caused by the effective stoichiometric displacement of H^+ ions (or OH^- ions) across the coupling membrane of the mitochondria, and that the $\Delta p\text{H}/\text{O}$ and $\Delta \text{H}^+/\text{O}$ values can be properly used to derive the $\rightarrow \text{H}^+/\text{O}$ quotients.

ATPase system. Fig. 4a shows a typical time course of $\Delta p\text{H}$ and $\Delta \text{H}^+/\text{P}$ on injecting $0.1 \mu\text{mole ATP}$ in $10 \mu\text{l. } 0.15 \text{ M oxygen-free potassium chloride}$ into $6 \text{ ml. mitochondrial suspension (6 mg protein/ml.)}$ in 'normal medium' containing 1.0 mM EDTA , but no substrate, at 25°C . Under these conditions the activity of the adenylate kinase is very low¹¹. There is a fairly rapid acidification of the suspension medium, followed by a slower, approximately exponential decay of $\Delta p\text{H}$ towards a value corresponding to $\Delta \text{H}^+/\text{P} = 0.8$. Experiments such as that of Fig. 4b, in which $6 \mu\text{g oligomycin per ml. plus } 5 \times 10^{-5} \text{ M DNP}$ were present, confirm that the final value of $\Delta \text{H}^+/\text{P}$ represents the acidification due to the chemical reaction $\text{ATP} + \text{H}_2\text{O} \rightarrow \text{ADP} + \text{P}_i + (0.76-0.80)\text{H}^+$ at $\text{pH } 7.0-7.1$. The uncorrected height of the peak in the experiments of Fig. 4a represents a total $\Delta \text{H}^+/\text{P}$ quotient of 2.08, or a quotient of 1.30 on subtracting the base-line value of 0.78. Extrapolation to correct for $\Delta p\text{H}$ decay is more difficult in this type of experiment than in the oxidation-reduction experiments because the rate of acidification is considerably slower initially and decreases as the ATP concentration falls during hydrolysis. We adopted the empirical method of extrapolating to the point of intersection of the straight lines representing the initial rate of pH fall and the initial straight portion of the subsequent $\Delta p\text{H}$ decay. The value is thus corrected to 1.49 in the experiment of Fig. 4. The extent of the side reactions for ATP hydrolysis was determined by the fraction of the overall rate that is oligomycin ($6 \mu\text{g/ml.}$) insensitive. In the typical mitochondrial preparation used for the experiment of Fig. 4 the oligomycin-insensitive ATPase represented 22 per cent of the total ATPase, and, accordingly, the corrected value of the $\Delta \text{H}^+/\text{P}$ quotient is 1.91. Several groups of similar experiments on four different batches of mitochondria have given a mean corrected $\Delta \text{H}^+/\text{P}$ quotient of 1.88 ± 0.09 . Conversely to the $\Delta \text{H}^+/\text{O}$ quotients, the $\Delta \text{H}^+/\text{P}$ quotients have been found to be suppressed by oligomycin ($6 \mu\text{g/ml.}$), but

unaffected or slightly enhanced by antimycin A (0.12 ml.) or by rotenone ($0.4 \mu\text{M}$). As described for the case of the electron transport system, by shifting the peak of the electron transport system, by shifting the pH upward as the peak of $\Delta p\text{H}$ is reached during ATP hydrolysis, the pH changes in the suspension medium caused by the ATPase system can be shown to be due to an effective displacement of H^+ ions through the coupling membrane and not to the net production or absorption of H^+ ions during the synthesis or breakdown of a hypothetical $\text{X} \sim \text{I}$ compound.

Ion secretion and electron translocation. There is a difference of opinion as to whether the 'secretion of H^+ ions' by continuously respiring mitochondria in response to the addition of divalent cations or of valinomycin, gramicidin is a primary process⁸, or whether it is a consequence of the 'active' uptake of the cations⁸; and we have therefore made a preliminary examination of this question for the case of the stoichiometric respiration-driven H^+ ion translocation observed in our experiments. Substituting a miniature flowing liquid junction (to be described in detail elsewhere) for the normal saturated potassium chloride junction of the reference electrochemical system, we have observed that, under appropriate conditions of pH and temperature, the limiting $\Delta \text{H}^+/\text{O}$ quotient for β -hydroxybutyrate oxidation is not significantly affected by replacing the $0.15 \text{ M potassium chloride}$ of the suspension medium by an equal concentration of sodium chloride or choline chloride, or by substituting 0.25 M sucrose for the salt. The presence or absence of $3 \text{ mM magnesium chloride}$ in the foregoing media was found to be without effect on the $\Delta \text{H}^+/\text{O}$ quotient. The K^+ content of the mitochondria in these experiments gave an equilibrium external K^+ concentration of $5 \times 10^{-4} \text{ M}$; it was observed, by means of a K^+ -sensitive glass electrode, that in the sucrose medium containing $3 \text{ mM magnesium chloride}$, and in the choline chloride medium, the respiration-driven outward H^+ displacement was accompanied by an uptake of K^+ ions. However, the K^+ ion uptake commenced slightly later than the H^+ displacement, was much less in magnitude than the H^+ displacement, and the subsequent K^+ extrusion was complete or showed a significant reversal about half-way through the time course of the $\Delta p\text{H}$ decay. We conclude that the respiration-driven H^+ translocation is probably an integral consequence of the passage of electrons and hydrogen atoms in opposite directions through the vectorially organized respiratory chain system of the mitochondrial membrane; and in this sense the respiration-driven displacement of H^+ or acid equivalents across the coupling membrane can probably be classed as "primary secretion of H^+ ions".

In the case of the ATPase-driven H^+ translocation, also seems probable, as will be described elsewhere, the cyclic transitions of mobile chemical groups through different states of ionization and hydration give rise to the passage of electrons and hydrogen atoms across the ATPase system in opposite directions.

Summarizing the experimental findings: (1) Oxidation-reduction through the electron-transport chain and ATP hydrolysis through the ATPase system each results in the translocation of protons outwards through the mitochondrial membrane system. (2) The stoichiometry of the ATPase system closely approximates to a $\text{P}/\rightarrow \text{H}^+$ quotient of $1/2$, while the $\rightarrow \text{H}^+/\text{O}$ quotients for succinate and β -hydroxybutyrate oxidation approximate closely to 2 and 6 respectively; thus making the product of the $\text{P}/\rightarrow \text{H}^+$ and $\rightarrow \text{H}^+/\text{O}$ quotients for succinate and β -hydroxybutyrate close to the known P/O quotients of 2 and 3.

These observations are in close accord with the basic principles of the chemiosmotic hypothesis of oxidative and photosynthetic phosphorylation, but show that the following changes of detail are required in Mitchell's original formulation¹: (i) As already surmised², the polarity of the system corresponds to a lower electrochemical potential of H^+ inside than outside the coupling membrane (higher pH

Fig. 4. Time course of $\Delta p\text{H}$ and $\Delta \text{H}^+/\text{P}$ during hydrolysis of ATP at 25°C . ATP ($0.1 \mu\text{mole}$ in $10 \mu\text{l. } 0.15 \text{ M oxygen-free potassium chloride}$) injected into $6 \text{ ml. anaerobic mitochondrial suspension in 'normal medium' containing } 1.0 \text{ mM EDTA}$ at vertical arrows. Curve a, no addition; curve b, plus $5 \times 10^{-5} \text{ M DNP}$ and oligomycin ($6 \mu\text{g/ml.}$)

re negative electric potential), the reverse of that originally assumed. (ii) The $\rightarrow H^+/O$ and $\rightarrow H^+/P$ stoichiometries are double those originally assumed. (iii) Owing to the electrochemical potential differential of H^+ ions across the coupling membrane required to cause a given ising effect on the oxido-reduction and ATPase equilibria only half that previously estimated; that is, a differential of 3.5 pH units with no membrane potential or membrane potential of 210 mV with no pH differential could be sufficient to poise the ATP/ADP quotient central a P_i concentration of 10 mM.

The latter point is particularly helpful to the chemi- nical interpretation of the coupling mechanism because brings the pH and electric potential differentials required the hypothesis within the physiological limits usually accepted for these variables (see Mitchell⁴). As shown elsewhere, the chemiosmotic hypothesis is now able to provide as realistic a model of oxidative phosphorylation the more fashionable chemical hypothesis, and in particular it affords a very simple explanation of the tion of classical uncoupling agents such as dinitrophenol, mitochondrial swelling phenomena, of the uptake and coupling effects of polyvalent metal ions, of the special mechanism of uncoupling by valinomycin and gramicidin, and of the pseudo site-specific inhibition of respiration by organic cations such as guanidine and its derivatives⁴. Other accounts of the work presented in this article and a

separate account of the present status of the theory of chemiosmotic coupling will be published in due course.

We thank Dr. Brian Chappell, Dr. G. D. Greville and Dr. Andre Jagendorf for helpful discussion, Prof. E. C. Slater for encouragement, and Mr. R. Mitchell for assistance.

STRUCTURE OF CONDENSED TANNINS

By L. L. CREASY* and Dr. T. SWAIN

Low Temperature Research Station, Cambridge

MOST of the work that has so far been carried out on the structure of condensed tannins (flavolans) has been concentrated on the possible modes of polymerization of the hydroxyflavan-3-ols (for example, (+) catechin, 2)¹⁻⁵. The polymerization of hydroxyflavan-3,4-diols (for example, IIa,b), on the other hand, has been less completely investigated, although it is believed that they are intimately concerned in the formation of flavolans⁶⁻⁸, and model experiments have shown that the hydroxyl group at C-4 readily forms carbonium ions in acid solution (for example, III) which react with nucleophilic centres similar to those at C-6 and C-8 in the commonly occurring flavan-3-ols and -3,4-diols (for example, Ia, Ib, IIa and Ib)⁹⁻¹⁰. Indeed, several workers^{2,11,12} have suggested that the flavolans are formed from flavan-3,4-diols by linkages between C-4 of one unit and C-8 (ref. 13) (or C-6, ref. 9) of another (for example, IV). Freudenberg² has further postulated that such structures would be readily cleaved by acid treatment to yield the parent diols (for example, II) or its reaction products (for example, the corresponding anthocyanidin, VI).

III: R = \oplus
(Carbonium ion)

In spite of this hypothesis, it has been suggested that the naturally occurring flavan dimers (biflavans) which have so far been investigated¹⁴⁻¹⁶, and which yield on treatment with dilute acid under relatively mild conditions (for example, 0.1 N HCl for 5 min at 100°)¹⁴ a flavan-3-ol (either Ia¹⁶ or Ib^{14,15}) and a second flavan moiety (which in all cases¹⁴⁻¹⁶ gives cyanidin (VI) on heating in stronger acid), have structures involving either a hemiacetal¹⁴,

ether^{15,17} or hemiketal¹¹ linkage between the hydroxyl group at C-3 of the flavan-3-ol and one of the hydroxyl groups of the pro-anthocyanidin moiety. Geissman and Dittmar^{18,19}, on the other hand, have adduced evidence that the biflavan from avocado seed (*Persea gratissima*), which yields catechin (Ia) on mild acid hydrolysis, has the structure Va. They have further suggested that the most commonly occurring polymeric leucoanthocyanins (that is, flavolans which yield cyanidin on acid treatment) are formed by extensive self-condensation of (III) via (IV), but that when a flavan-3-ol (for example, catechin (Ia)) is present a biflavan can be produced (for example, Va-e) which is relatively stable and is incapable of further condensation since it lacks a hydroxyl group at C-4' (ref. 1).

We have been studying the physiology of flavanol formation in the leaves of the wild strawberry (*Fragaria vesca*) and have shown that this tissue produces, besides (+)-catechin (Ia) and a number of flavolans of apparently increasing complexity, a biflavan which yields (+)-catechin (Ia) and cyanidin (VI) by suitable acid treatment, and is thus similar to the biflavans from avocado^{18,19} and *Gleditsia triacanthos*¹⁸. absorptivity of the solutions of the biflavans from strawberry and avocado, both in methanol and 70 per cent sulphuric acid²⁰, and of their adduct with vanillin in 70 per cent sulphuric acid²¹ are closely similar, as is the yield of cyanidin formed by heating either of them in *n*-butanol-concentrated hydrochloric acid (9:1)²¹ for 1 h (Table 1). However, the R_F values of the two compounds are different in most solvent systems and it must be assumed that the two compounds are stereoisomers. Support for this assumption comes from the fact that, after epimerization in water at 120° for 2 h²², the strawberry biflavan gives six components separable on cellulose thin-layer plates in 5 per cent methanol, three of which have identical R_F values with the products of epimerization of the avocado compound.

In order to obtain more evidence as to the nature of the strawberry biflavan, we have examined the products obtained by treating an aqueous solution of a mixture of (+)-catechin (Ia) and the flavan-3,4-diol racemate (IIa,b) produced by the reduction of naturally occurring 2,3-dihydroquercetin (2,3-*trans*) with sodium borohydride²³, with cold 0.4 *N* hydrochloric acid for 5 min. The acid was removed with di-*N*-octyl methylamine in chloroform²⁴, and the resultant mixture separated by preparative paper-chromatography in butanol/acetic acid/water (BAW, Table 1), giving two compounds *CA* and *CB* (see Table 1) in yields of 50 per cent and 37 per cent respectively (based on the (+)-catechin used). The R_F value of the faster-running major component *CA* on paper chromatograms and on three different thin-layer supports in various suitable solvent systems is identical with that of the strawberry biflavan (Table 1). Furthermore, both *CA* and *CB* have the same spectral properties as the strawberry compound (Table 1) and produce the same six components on epimerization²². It should be noted that both *CA* and *CB* give (+)-catechin (Ia) on treatment with dilute acid and are presumably stereoisomers at C-4 (Vb and Vc). From the chromatographic behaviour of the known isomeric flavan-3,4-diols²², and the fact that sodium borohydride reduction of the dihydroflavonols gives mainly 3,4-*trans* compounds²⁵, it appears possible that the major synthetic dimer, and therefore the strawberry biflavan, is the 2,3-*trans*-3,4-*trans*-2',3'-*trans* isomer (Vb); *CB* therefore being Vc. Naturally, more exact criteria^{22,25,26} are required to confirm this possibility.

When (-)-epicatechin (Ib) was mixed with the flavan-3,4-diol racemate (IIa,b) and treated as above, two different compounds were produced, *EA* and *EB* (50 per cent and 22 per cent yield of each based on the (-)-epicatechin). With suitable acid treatments, these compounds gave (-)-epicatechin (Ib) and cyanidin (V) and both had almost identical spectral properties as those of the biflavan isolated from the seeds of *Theobroma cacao*²⁷. However, the R_F values of both synthetic compounds are different from that of the natural product. Epimerization

of both *EA* and *EB* gives six separable products (two which are identical in R_F value with two of those produced from *CA* or *CB*, but the cocoa biflavan only yields the separable components, one of which corresponds with while another corresponds with *CA*. Since *EA* and must be IVd and IVe, it appears probable that the co-biflavan may differ in the stereochemistry at C-2 and (V), and is perhaps the 2,3-*cis* isomer. If this were the case both flavan moieties would have the same configuration at C-2 and C-3. It is, of course, possible that some other structure is involved, but since the octamethyl ether of the cocoa compound yields 5,7,3',4'-tetra-*O*-methyl-epicatechin and 5,7,3,4'-tetra-*O*-methylecyanidin on treatment with hot acid¹⁴ it must be concluded that the phenolic hydroxyl groups are not involved in the linkage between the flavan nuclei, and structures such as those suggested by Roux¹¹ and Hergert¹² for the formation of polymers involving a link between C-4 and the oxygen at C-7 of the second flavan are unlikely.

Finally we have examined the properties of the water insoluble, methanol-soluble polymer *LP* which is produced when the flavan-3,4-diol (IIa,b) is treated with cold acid¹² in the absence of any other nucleophile. This compound is immobile in all solvent systems and shows the expected lower reactivity with vanillin in 70 per cent sulphuric acid^{21,28}, but gives a somewhat higher yield of cyanidin than found with natural polymers of this type^{7,13} (Table 1). It also yields no (+)-catechin or (-)-epicatechin on mild hydrolysis: when the hydrolysis is carried out in the presence of (+)-catechin, however, it does give small yields of both *CA* and *CB*, thus indicating that the C-links are broken by such treatment. Since Quesnel²⁹ has shown that the natural cocoa flavanol yields (-)-epicatechin on mild acid hydrolysis, it must be concluded that Geissman and Dittmar's hypothesis with regard to the structure of the flavanols is not wholly correct.

It appears probable, instead, that condensed tannins of the flavanol type are complex, branched, three-dimensional structures in which the majority of the repeating units are nuclei derived from hydroxyflavan-3-ols and 3,4-diols. It is also possible that nuclei derived from flavan-4-ols and flavan-4-ols³⁰ (flavylium pseudobase) may be involved. It is considered that the flavan nuclei will be linked, initially, mainly by bonds between C-4 of one of the flavan-3,4-diol units, and either of the nucleophilic sites, C-8 (ref. 13) or C-6 (especially the latter for those hydroxy flavans having a resorcinol-like A-ring, for example, VII) of another hydroxyflavan. In the case of flavans having a pyrogallol-type of substitution in the B-ring (for example, VIII) there will also be the possibility of links to the nucleophilic C-2' and C-6' positions (cf. refs. 3 and 4). In such polymers flavan-3-ol nuclei linked via C-4 of a flavan-3,4-diol, would form relatively stable end units to branches, and the parent flavan-3-ol would thus be released on mild acid treatment²⁹; similarly,

van-3,4-diol nuclei present in the structure linked as di units, or only through other diols, would also be released on acid treatment to give in part anthocyanidins. Branch points would occur wherever two or more of the potential reactive centres in any one flavan were involved in linkage. Subsequent changes in the initial polymer may be induced by oxidation^{3,4} (which might be better regarded as being due to one-electron coupling reactions; compare refs. 31, 32), by the formation of bonds between the electrophilic centre at C-2^{1,2} and the nucleophilic sites mentioned earlier, and by the formation of internal ether-type links^{30,33,34}. Of course, other suitable nucleophiles or electrophiles (such as lignin precursors, amino-acids, etc.) may also be incorporated into the whole flavanol molecule, and links may be formed to other macromolecules in the cell²⁸.

In spite of our doubts about Giessman and Dittmar's proposals^{18,19} for the flavanols, we believe that the results presented here support their hypothesis regarding the structure and stability of the biflavans. Furthermore, this theory may be extended to explain why the only natural flavan-3,4-diols so far isolated which have had their structure and stereochemistry unequivocally proven lack a hydroxyl group at C-5 (for example, VII, $R_1 = \text{OH}$). The lack of this hydroxyl group not only

enhances the stability of the flavan-3,4-diol itself by reducing the nucleophilic activity of C-6 and C-8, but also reduces the probability of its reacting with a corresponding flavan-3-ol. It is noteworthy that in spite of extensive investigations⁶ no biflavans corresponding to IV having a resorcinol-type substitution in either or both A rings have so far been isolated.

One of us (L. L. C.) thanks the National Science Foundation for support (grant 43129). We thank Prof. T. A. Giessman and Dr. H. K. F. Dittmar for allowing us to see their results before publication, and for a gift of avocado biflavan from Dr. Dittmar.

INTERSTIMULUS INTERVAL AND NUMBER JUDGMENT

By D. JONES and DR. A. ELITHORN

External Scientific Staff, Medical Research Council, Institute of Neurology and Royal Free Hospital, London

ON the basis of previous experiments it was suggested by one of us that the interference which occurs when subjects respond to two single stimuli, separated by very short time-intervals, was determined by both perceptual and motor components¹. In a more recent paper it has been shown that some subjects can, under certain conditions, process simple stimuli simultaneously and independently². In the experiments reported here we examined some aspects of the perceptual field which may determine the effective size of the so-called span of apprehension. The size of the span of visual apprehension is a subject which has attracted a fair amount of psychological investigation. Less work, however, has been done on the problem of the necessary length of the time-interval needed between two stimuli to allow two independent judgments, or on the interaction between this interval and the content of the two stimuli. The many investigations into the span of visual apprehension all agree that the accuracy of judging the number of briefly displayed objects decreases with increasing stimulus number, and

that, under most conditions of presentation, the threshold criterion of 50 per cent correct responses occurs with 6-7 stimulus objects. Three experiments on the effect of interstimulus interval on the perception of numerosity are described.

In the first experiment 6 subjects were asked to report the number of neon bulbs illuminated in two presentations, separated by time-intervals of 50, 100, 200, 350, 600 and 900 msec. Because earlier experimental findings suggested that some subjects could process simple stimuli independently if they were presented in the opposite half-fields, the display was designed so that pairs of stimuli could be presented in the same half-field or in different half-fields.

Sixty-four small neon bulbs were mounted behind small apertures in a black display board in the form of four small 4 in. x 4 in. square arrays which formed the corners of a square of side 1 ft. At the centre of the display board there was a small warning light which the subject was instructed to use as a fixation point. The warning light

came on 1,200 msec before the start of each stimulus situation and remained on for 800 msec.

The pairs of stimuli were arranged in sets of 36, each set consisting of all combinations of 1-6 lights in the first stimulus, with 1-6 lights in the second stimulus. The number sequences, the spatial relationships and the time separation of the stimuli were determined by a balanced, randomized design. Each subject was tested twice, each session consisting of 6 sets of stimuli, separated by a rest interval of 2 min. The subjects were 6 female medical students at the Royal Free Hospital, their mean age being 24 years. The subject's instructions were to give a verbal report of the presented number for both stimuli in each situation.

The first of each pair of stimuli could be presented in any of the 4 positions and the second followed it at the selected interval in any of the other 3 positions. The duration of the neon flash was 40 msec and the time intervals were measured from the start of the first stimulus to the start of the second. The subject was seated 8 ft. from the display; the visual angle sub-tended by the distance between the warning light and the neon positioned at each outermost corner was 5 deg.

The results of this first experiment are given in Table 1. The findings are disappointing. An analysis of variance showed no significant position effect and that the effect of the value of the time-interval on the number of correct responses was significant only at the 5 per cent level. It was, however, clear from the overall performance of our subjects, and from their introspective reports, that the effects of the variables were obscured by the fact that the task was too difficult under all conditions. It seemed likely that at least three factors were contributing to this. In the first place, the stimulus arrays were outside central vision, making the resolution of each stimulus difficult. This was confirmed in a subsidiary experiment in which the subjects reported the number of neons presented in single groups, in one condition with central fixation and random presentation of the array, and in a second condition in which they were told in which array the stimulus would appear and were allowed to fixate on that position. A second difficulty was that the use of a peripheral stimulus and the unbalance of expectancy, created by the fact that the second stimulus occurred with equal frequency in two contralateral and one unilateral quadrants, made it very difficult for subjects to inhibit eye movements occurring between the two stimuli. These eye movements were both reflex towards the first stimulus and, if this was inhibited, 'expectant' towards the contralateral half-field. Thirdly, the experimental design did not allow enough practice.

In order to overcome these difficulties, we decided to leave for the time being the examination of the half-field effect and to design an experiment which would provide reliable information on the effect of the time-interval. An alternative display was designed and built.

In the second experiment 60 small neon bulbs were arrayed in 3 concentric hexagonal rings. The outermost hexagon had a radius of 2 in. and was made up of 30 neons which formed 1 functional group. The middle hexagon had a radius of 1.2 in. and contained 18 neons and the inner one, with a radius of 0.8 in., was made up of 12 neons. The 30 neons in the 2 inner hexagons formed the second functional group. As in the first experiment, there was a warning light at the centre of the display.

Table 1

	50	100	Interval (msec)		600	900	Average for all intervals
			200	350			
Stimuli in opposite half-fields	28.1	34.7	28.8	32.2	36.8	36.1	32.8
Stimuli in same half-fields	30.6	26.4	31.9	31.9	35.4	41.0	32.9
Average for all conditions	28.9	31.9	29.9	32.2	36.3	37.7	32.8

Percentage of correct pairs of responses for all 6 subjects in Experiment 1 at each of the time-intervals is given separately for the presentations made in the same and the opposite visual half-fields.

The visual angle sub-tended by the display at the view distance of 8 ft. was less than 2.5°.

The stimuli were arranged in basic sets of 36 pairs consisting of all combinations of 1-6 neons in the first stimulus, with 1-6 neons in the second stimulus. The sets stimuli were presented in the 2 sequences inside followed by outside and outside followed by inside. Each subject was required to judge the presented number for 2 practice and 4 test sets of stimuli, at each of the following intervals: 0, 50, 100, 150, 200, 250, 300, 350, 400, 500, 700 and 900 msec.

Each time-condition was examined separately, half the subjects taking the series in ascending order and half the descending order. The subjects were free to report the total number of lights for both stimuli or to make separate estimates. The subjects were students or members of staff at the Royal Free Hospital. Eight were female and 4 were male, the mean age for the group being 24 years.

The results of this experiment are summarized in Fig. 1. At intervals of 200 msec and longer, all 12 subjects made separate reports for each member of the stimulus pairs. At the shorter time-intervals most of the subjects made single reports in response to each pair of stimuli. If the analysis presented here the report is regarded as error when the total number reported was different from the total number presented. In Fig. 1 the results are presented for both the descending and ascending groups. At all intervals, except 300, 700 and 900 msec, the ascending group made more errors than the group taking the time-intervals in descending order.

The differences in the error curves for the 2 groups of subjects strongly support the view that different mechanisms or strategies are employed at the very brief and longer time-intervals. Both groups show evidence of practice effect at the task of judging stimuli separately by the longer time-intervals, that is, in the range from about 100 to 900 msec. The ascending group performs relatively badly at the first intervals they encounter in this range; but at the longest intervals which are the first encountered by the descending group, the performance levels are reversed. At the simultaneous condition and the 50 msec time-interval the prior experience of the groups of the shorter intervals is about the same and the performance levels are almost identical. Both curves show fewer errors when the stimuli are presented simultaneously.

Fig. 1. The error curves obtained in the second experiment for the two groups of 8 subjects—ascending and descending orders of time-intervals. ---, Group 1 ascending; —, group 2 descending

Fig. 2. Relationship between percentage errors and time-interval for all 6 subjects in the third experiment

taneously or with an interval of 50 msec than they do when the interval is 100 msec, both curves showing maximum errors at this time. Studying the error curves for each subject showed that 10 out of the 12 had a peak in their error scores at the 100 msec interval. The other 2 subjects were both in the descending group and both had a peak in their error curves at the 50 msec interval.

In an attempt to narrow the limits within which the peak difficulty occurred, a third experiment was undertaken. Using a Latin square design to balance practice and fatigue effects at the different time-intervals, 6 new subjects undertook 6 sessions, each of 2 practice sets and 4 test sets, each set consisting of 36 pairs of stimuli, arranged in a balanced design, as in the previous experiment. Each session was at one of the following 6 intervals: 40, 60, 80, 100, 120 and 140 msec.

The error curve for the group is given in Fig. 2. The results clearly confirm the findings of the previous experiment and indicate that the peak difficulties lie between 60 and 100 msec.

In this last experiment each subject undertook one session at each time-interval, the order of time-intervals being different for each subject. Practice effects between sessions were marked and the experiment provides no evidence on individual differences.

The analysis presented here takes no account of the numerosity of the stimuli or of order effects in relation to the relative numbers of neons in the first and second stimuli. Errors, as might be expected, were more frequent with the larger total numbers and were greater when the larger number was presented first, as contrasted with the

situation when the second stimulus was the larger. These findings will be presented and discussed in detail later, but clearly the time-course of the error curve calls for brief comment.

In an earlier investigation on reaction time responses to successive stimuli separated by short intervals, it was observed that delays in the second response were not maximal at the shortest intervals³. This observation was critical to Welford's theory of a psychological refractory period, although Hick and Welford⁴ suggested that the apparent exceptions to the theory might be due to subjects' grouping, or responding to both stimuli as a single unit, at the very short intervals. In the work recorded here it is obvious that, with almost no clues for a spatial separation, subjects must be grouping the stimuli when presented simultaneously. It is also clear that at the longest intervals the stimuli are treated as independent. The poor performance at the 50 and 100 msec intervals cannot be due to a grouping strategy. For the ascending group it represents a failure to maintain such a strategy as the interval increases. For the descending group it may be seen as a failure, as the intervals decrease to attain a grouping strategy which is achieved at the shortest intervals.

As will be reported elsewhere, each stimulus impairs the perception of the other and this can be related to the phenomena of metacontrast and of apparent movement. Subjects frequently reported apparent movement effects at the short time-intervals. The perception of two discrete stimuli as a single stimulus in motion would clearly impair the perception of numerosity. Unfortunately, the literature on the time relationships of both metacontrast and apparent movement is, in both instances, complex. However Alpern⁵, who among others has reviewed the work on metacontrast, himself demonstrated a maximum masking effect when the interval between the stimuli was in the region of 100 msec.

While it is tempting to interpret the failures in the perception of numerosity, in terms of the apparently more basic processes of metacontrast and apparent movement, it is perhaps more useful to relate all these to the characteristics of central interpretative mechanisms. It is hoped to develop this approach in relation to a more detailed description of the present findings.

CONTROL OF THE COMPETENT STATE IN *Pneumococcus* BY A HORMONE-LIKE CELL PRODUCT: AN EXAMPLE FOR A NEW TYPE OF REGULATORY MECHANISM IN BACTERIA

By DR. ALEXANDER TOMASZ
The Rockefeller Institute, New York

COMPETENCE or 'transformability'—the ability of some bacterial cells to take up biologically active DNA molecules and undergo genetic transformation—is a genetically determined property of some *Pneumococcus* strains. It has been known for some time that in pneumococcal cultures passing through a typical growth cycle this genetic potency gains phenotypic expression in most of the cells only during a relatively short 'competent' phase of growth¹. During this short phase, the cell population becomes highly uniform with respect to competence: the majority of the cells can be transformed by multiply-marked DNA, and there is evidence that all the individual cells present express the competence property.

The time course of this expression during growth shows some unique features: once an induction period is passed in which competence is low or undetectable, there is an abrupt and fairly 'synchronous' development of transformability at a rate very much faster than the growth rate of the culture. Under these conditions, the maximal competence is usually followed by a rapid decay of this property. A typical time course of such an expression process is illustrated in Fig. 1.

The cause of the delayed and abrupt appearance of competent cells in pneumococcal cultures has been a puzzle ever since the discovery of the existence of a 'competent phase' during which these bacteria are capable

of undergoing genetic transformation². Since in some complex growth media the competent phase of pneumococci seemed to develop close to the onset of the stationary phase of growth, it was suggested that transformable cells are physiologically abnormal organisms (for example, cells deficient in ability to grow) which accumulate in the culture as the growth medium becomes exhausted in some nutrients^{3,4}.

However, more recent investigations revealed no support to this interpretation. Instead, it was proposed that the rapid accumulation of competent cells should be regarded as a shift to a distinct physiological state⁵. This point of view has already been expressed by a number of authors^{2,6}, but our experiments yielded new evidence in support. (1) It was found that pneumococcal cultures grown in chemically defined media develop the competent phase in a critical cell concentration range, but independent of the 'closeness' of the stationary phase or the growth rate of the culture^{7,8}. (2) Competent pneumococci seem to be actively growing cells as indicated by their sensitivity to penicillin⁹ and by the fact that the competence of a culture can be stabilized in a chemostat under conditions where slow-growing cells would be rapidly diluted out⁷. (3) Finally, the detection of small quantities of biologically active DNA in sterile filtrates of growing pneumococcal cultures near their peak of competence suggests that this property has a biological 'value' for *Pneumococcus* in that it may equip these bacteria with a mechanism for gene exchange¹⁰. In this unique recombination mechanism, gene transfer depends on the random collision of DNA molecules and cells. Since the rate of this process is a function of the cell concentration and the DNA concentration as well, the synchronous appearance of competence in the majority of the cell population makes the chances for genetic transformation optimum.

If one accepts this interpretation, then the development of competence may be regarded as the phenotypic expression of an important pneumococcal character which at low cell concentrations is 'repressed' in most members of the cell population.

Fig. 1. The time course of development of competence during growth of a *Pneumococcus* culture

Fig. 2. Cell-to-cell transfer of the competence property

In the past three years, the mechanism of this delayed and synchronous expression was the subject of systematic investigations undertaken in our laboratory. It became apparent that the abrupt expression of competence does not depend on a general phasing of the life-cycles of the individual cells, since there is no detectable sign of massive division-synchrony in cultures during the development of competence.

It seemed likely, therefore, that the uniform and synchronous expression of this pneumococcal character is ultimately controlled by some environmental or endogenous factor able to affect randomly dividing cells.

Investigations of the effect of culture conditions on the time course of development of competence have clearly shown that alteration of the medium composition by the bacterial growth (for example, 'detoxification' or selective removal of some medium components) was not responsible for the synchronous 'expression' of this property⁸. Furthermore, as has already been mentioned, cultures of pneumococci growing in synthetic media in which growth was regulated by varying levels of enrichment were found to develop competence at about the same cell concentrations regardless of the phase of growth or rate of growth of culture^{7,8}.

Recent attempts to identify the mechanism controlling the expression of competence led to the discovery of a unique regulatory mechanism. It was found that the expression occurs through a co-operative process in which cells in the competent state can transfer this property to incompetent bacteria in a rapid process mediated by a specific macromolecular product of the competent cells⁵. The essential features of this observation are reproduced in the experiment illustrated in Fig. 2. Washed suspensions of two pneumococcal cell types which were distinguishable by their different antibiotic resistance (resistance against sulphamylamide in cell-type A and resistance against micrococcin in cell-type B) were mixed in a test-

tube in fresh medium. Cells of type *A* were highly competent and were introduced into the test-tube at a concentration of 1×10^6 cells per ml.; cells of type *B* were incompetent and were present at a concentration of 1×10^7 cells per ml. The same concentration of the incompetent cells was also introduced separately into a (control) test-tube without cell-type *A*. Both tubes were incubated at 30° C, a temperature at which the spontaneous development of competence is inhibited⁵, and the transformability of the two cell types was determined by exposing aliquots to a DNA carrying the streptomycin resistance marker. The transformants were selectively scored in two different antibiotic-containing media: in medium *A* (containing sulphanilamide and streptomycin) to count transformed *A* cells and in medium *B* (containing micrococin and streptomycin) to count transformed *B* cells.

Fig. 2 shows that whereas cell-type *B* incubated alone in the control tube remained incompetent, the same bacteria in the mixed culture tube rapidly developed a high level of competence as a result of some interaction with the competent cells of type *A*. There was no significant change in the numbers of cells present during the short span of the experiment. It was calculated that about 80–90 per cent of all the type *B* cells have become competent by the 'activating' effect of cell-type *A*, in spite of the fact that these latter made up only about 10 per cent of the total population. The competence of the type *A* culture did not change during this process.

Next the mixed culture experiment was repeated in a modified form: the cultures of both cell types were introduced into the separate compartments of a U-shaped glass tube which was divided in two compartments by a 'Millipore' membrane. During incubation at 30° C, the filtrates of the two cultures were mixed by continuous pumping of the medium through the 'Millipore' membrane. Under these conditions, physical contact between the competent and incompetent bacteria was excluded. Table 1 shows that the cell-to-cell transfer of competence did not necessarily require physical contact of the organism but could occur through the mediation of some filterable cell product. The relatively low efficiency of competence induction was attributed to the low concentration of cell-free 'activator' substance and its extreme lability⁵.

Table 1

Cell type	No. of transformants per ml after incubation for	
	30 min	60 min
<i>B</i> (incompetent) alone	0	0
<i>B</i> in mixed culture with <i>A</i> (competent)	5.7×10^4	5.7×10^4
<i>B</i> in U-tube with <i>A</i>	300	1.3×10^4

Cell-to-cell transfer of the competence property by way of a soluble cell product.

The activator substance, responsible for the cell-to-cell transfer of competence, was afterwards isolated from competent pneumococci. Purified preparations of this heat-labile material could convert incompetent bacteria to competence in a fast 'reaction', the rate depending on the concentrations of both the activator and the cells⁵.

The pH optimum of this process was about 7.7, and the biological activity of activator preparations could be greatly enhanced in the presence of 0.05–0.07 M mercaptoethanol. Low concentrations of various proteolytic enzymes (0.1 µg/ml.), such as trypsin, chymotrypsin and subtilisin, inhibited the activation of incompetent cells by activator preparations, whereas these enzymes had no effect on the transformation of already competent cells by DNA. This observation suggested that the activator is a protein. Fractional elution of the activator substance from the cell debris yielded preparations with high specific activity: extracts with less than 0.2 µg protein/ml. could convert 10^6 cells to the competent state at 37° C in 10 min. The activator substance appears to be of fairly high molecular weight, since it is not retained during chromatography on 'Sephadex G25' columns. A small retention can be achieved on 'Sephadex G75' (Fig. 3).

The activator seems to be specific for *Pneumococcus*, since *Bacillus subtilis* and *Haemophilus influenzae* cultures in their incompetent phase of growth could not be converted to competence by pneumococcal activator. During the activation process the surface of the pneumococcal cells seems to undergo significant changes: a new antigenic determinant appears¹ and the bacteria develop a capacity to bind DNA and become transformed by it¹². Subsequent investigations have shown that the rapid disappearance of competence which usually follows closely the brief maximal competence of the culture can be correlated with another cell-produced factor, called 'inhibitor'. After pneumococcal cultures reach a certain density their filtrates rapidly become enriched in this inhibitor which can block the action of the activator and prevent further spread of competence⁵. Thus, it appears that the transient and synchronous expression of the competence character during growth is controlled at the level of the pneumococcal population by extracellular factors manufactured by the cells themselves.

The attainment of a transient physiological state in a population by such an 'induction' process seems to be a novel phenomenon among bacteria, and it raises a number of interesting questions concerning the nature of the cell interactions involved in such a process. (It is important to distinguish between the cellular 'communication' involved in the propagation of competence and the cell interactions which occur during the cell-to-cell transfer of episomal or chromosomal material. These latter interactions serve the 'dispersal' of genetic material in a population of bacteria while in the case of competence a physiological state is propagated.)

In the traditional view bacterial populations are characteristically lacking mechanisms for specific inter-cellular communication. This is contrasted with cell populations of higher organisms in which hormonal mechanisms are known to induce and reinforce the expression of many physiological properties and control differentiation.

The control of competent state in pneumococci forces one to revise this view. Since the activator—a cell-produced chemical—seems to impose a high degree of physiological homogeneity in a pneumococcal population with respect to competence, one is forced to conclude that in this case bacterial population can behave as a biological unit with considerable, although only temporary, co-ordination among its members. In a sense, this situation then resembles hormonal control—an example for a primitive, temporary 'differentiation' in bacterial populations.

One wonders whether this kind of control may not be operative in some other microbial phenomena also. It is

Fig. 3. Chromatography of pneumococcal activator on 'Sephadex G75'

well known that bacterial populations are able to undergo drastic changes in the physiological properties of the majority of the cells. Numerous examples for such massive non-genetic variability or 'modulations'¹³ are known: the list includes the variation in cellular components such as amounts of capsular material, intracellular lipid, carbohydrate and polyphosphate inclusions, qualitative and quantitative changes in the surface antigens and fimbriae (for review see ref. 14), cyst formation¹⁵, cyclic morphogenetic changes in cell shape¹⁶, sporulation¹⁷, changes in virulence¹⁸, changes in the biosynthetic capacity as it occurs in the production of tyrocidine¹⁹, bacitracin²⁰, edein²¹, and other bacterial polypeptide antibiotics.

In the absence of known endogenous causes, such as genetic variation or biological clock mechanisms, such gross physiological changes in a whole bacterial population are usually considered as the results of interactions between cells and their environment (using the term 'environment' in its broadest sense), even though in the majority of the cases the environmental signal invoking them is not known and the physiological significance of the change is usually little understood.

For the interaction between environment and cell population, two general and contrasting types of mechanisms can be considered. In the first type, each individual in the population would receive and recognize the environmental stimulus and respond to it in a continuous interaction with the environment and without any interaction with other individuals in the population. The homogeneity of the population with respect to the particular physiological state would then be the result of the basic uniformity of individuals as well as the uniformity of the environmental change. The derepression of metabolic pathways by the depletion of an end-product is at present considered as having such a mechanism.

In the second type of mechanism, a similar physiological response would originate in a radically different way. The environmental change would be first recognized by a small number of cells only; these cells would respond by 'converting' this environmental signal to a second and specific extracellular (chemical) signal, for example, the activator substance in the case of competence, which in turn would interact with the rest of the individuals of the population and convert them to the appropriate physiological state. In this 'hormone-like' mechanism, the physiological change in the majority of the cells does not occur by virtue of a continuous interaction with the environment but rather is called forth by a specific cell product. The homogeneity of the population with respect to the physiological character is determined here primarily by the specificity and effectiveness of the activator. (The terms 'hormone' and 'hormone-like' are used here in their broadest sense to indicate specific cellular products which have the biological function of co-ordinating individual cells of a cell population with respect to a physiological property. While this formulation includes the essence of the hormonal function, it clearly differs from the traditional definition of 'hormone' which restricts the use of this term to internal secretions of multicellular organisms. The need for a less stringently defined term for hormone-like functions was discussed in detail by J. Huxley, who proposed that such substances could, perhaps, be generally called 'activators'. 'Activator' should include all "chemical substances produced by organisms which exert specific functions in regard to correlation or differentiation"²².)

The 'hormone-like' role of activator in the cell-to-cell propagation of competence seems well established. Practically nothing is known, however, about the nature of the stimulus invoking the production of this substance. It was found that in a number of experimental systems, the prolongation of the induction period preceding the appearance of competent cells is caused by the apparent failure in the production of endogenous activator⁸.

Control by an extracellular activator is not restricted to the transformation system of *Pneumococcus*. A similar

induction system has been discovered independently by Pakula and Walczak²³ among some transformable strains of *Streptococcus*, and we found evidence for the existence of an activator of the pneumococcal type in a streptococcus strain¹² which is closely related to *Pneumococcus* (*Streptococcus viridans* D used in the work of Bracco *et al.*²⁴). More recently it was reported that the competence of a transformable *Bacillus cereus* strain also is regulated by an activator substance²⁵. Possibly, other transformation systems will be found to have similar cellular regulatory mechanisms.

At present, however, there seem to be only a few other well-established examples of such activator-mediated 'cell communications' among micro-organisms, and the control of competence in *Pneumococcus* and *Streptococcus* seem to be the first examples among bacteria in which such a mechanism can be clearly outlined.

Perhaps the most clearly understood other case is the chemotactic movement of some myxomycetes during their morphogenetic aggregation^{26,27}. A somewhat similar effect has been described in the induction of sporulation of vegetatively growing *Bacillus subtilis* by extracts prepared from sporulating cells²⁸. It may be worth while, however, to suggest the possibility that activators may also participate in the regulation of some bacterial 'phenotypic variations', a number of which have already been listed. Judging from the homogeneity of the competence property which the activator produces as well as from the extremely fast rate of the activation process, such activator mechanisms could greatly improve the uniformity and efficiency of cellular responses to some environmental change and in this way improve the adaptive potential of populations.

Another phenomenon which may perhaps be interpreted within the framework of such an activator mechanism is the loss of virulence of group-A streptococci during growth under reducing conditions. The value of this physiological change for the organism is not clear, but the mechanism of this effect may be taken as an example of how a rapid change in a property of a bacterial population may be coupled to an environmental change. Elliott has shown²⁹ that, in this case, the loss of virulence is associated with the loss of the antigenic M-protein from the cell surface as a result of the action of an extracellular protease. This enzyme is excreted by the cells in an inactive zymogen form and becomes activated by the reducing conditions produced in the anaerobic environment.

Clearly, an enzyme could be an ideal activator for the efficient regulation of a property in a cell population, and it may be interesting to consider the role of some bacterial exoenzymes as instruments in the regulation of some as yet unrecognized physiological states. If this were valid, then it is likely that the targets of such exoenzymes or other specific extracellular cell products would be primarily surface components of the bacteria. Interactions with bacterial surface structures can have extremely specific and far-reaching intracellular consequences, as is known from investigations of the mechanism of action of colicins³⁰ and adsorbed bacteriophage ghosts³¹.

Interactions between groups of cells through specific cell-products is, of course, quite common among higher organisms on all levels of cell associations and even in ecological relationships³². There are numerous examples of hormonal control in morphogenesis and differentiation, as well as in the 'integration of individuals of a population' through specific extracellular chemicals³³. The results discussed in this article suggest that the capacity for such a population-level control may already exist among micro-organisms. In addition to the highly efficient enzymatic control mechanisms (such as end-product control or repression), which operate in 'individual' cells of bacteria, 'populations' of these organisms may exhibit supra-cellular regulatory mechanisms also, which can efficiently control a physiological property in a large number of cells. At present, it is not known whether the pneumococcal

activator participates in the regulation of gene activity or operates entirely on the physiological level.

The fact that the transformable state in *Pneumococcus* is regulated by a specific cell product may be interpreted as emphasizing the evolutionary importance of transformation for *Pneumococcus*. This investigation was aided by a grant from the National Science Foundation (GB-2083) to Dr. R. D. Hotchkiss.

RATE OF CHROMOSOME DUPLICATION AT THE END OF THE DEOXYRIBONUCLEIC ACID SYNTHETIC PERIOD IN HUMAN BLOOD CELLS

By DR. C. W. GILBERT, S. MULDAL and DR. L. G. LAJTHA

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester

IN an earlier publication we considered the pattern of chromosome duplication at the end of the DNA synthesis period (*S* period) in human blood cells¹. One of the notable features was a difference in the rate of DNA synthesis between certain chromosomes, particularly so in one of the X-chromosomes of females, the 'hot' X-chromosome. Because of the intensive labelling of this chromosome at a time when most other chromosomes were unlabelled or only weakly labelled, the 'hot' X has been considered as being delayed in its duplication¹⁻⁴. This article analyses in more detail the labelling behaviour of the autosomes as compared with the 'hot' X-chromosome at the end of the *S* period.

Cultures of female peripheral leucocytes were prepared by the usual method⁵ with the difference that red cell agglutination was carried out by letting the sample stand (1 h) at room temperature and using phytohaemagglutinin *M* (Difco) only as a mitotic stimulant.

Labelling was carried out at minus 3 h with 0.2 μ Ci/ml. medium of tritiated thymidine (Radiochemical Centre, Amersham, spec. act. 12.3 mCi/ μ M). 'Colcemid' (Ciba, 0.04 ml./ml. medium) was added 1.5 h before termination of the cultures. Slides were prepared for autoradiography with Kodak 'AR 10' stripping film and exposed for 8 days.

A random sample of 224 cells in metaphase was selected for analysis. To ensure a proper random sample, cells in metaphase were rejected only for one or more of the following reasons: (a) an incomplete set of chromosomes; (b) an excessive overlap of any chromosomes that prevented them from being individually identified; (c) the cell crossed by a prominent 'background streak' of grains. Except for the criterion (c) the autoradiographic grains were ignored during selection.

After the selection of the cells had been made the autoradiographic grains over the whole sample were counted by two observers. For each cell the grains were put into three mutually exclusive classes: (a) *background grains*, grains which were not over any chromosome but within the boundaries of the metaphase plate; (b) *'hot' X grains*,

grains over the most heavily labelled chromosome in Group III (Denver classification); (c) *autosome grains*, all the other grains, that is, grains over all chromosomes except the 'hottest' in Group III.

A grain was taken to be over a chromosome if it was within a distance of one chromatid width. For the sake of brevity 'autosomes' will include the 'cold' X chromosome.

The results are shown in Table 1 and Figs. 1-3. For the purpose of analysis two distributions are shown: (a) cumulative distribution of the total grains over the cell, excluding the 'hot' X, that is, the sum of classes (a) and (c) (Table 1 and Figs. 1 and 2); (b) cumulative distribution of the grains over the 'hottest' chromosomes in Group III, that is, class (b) (Figs. 1 and 2).

(1) *Unlabelled cells*. From Table 1 we can infer that between 160 and 165 cells were unlabelled, and that the grains observed over these cells arise from a random distribution of background. Table 1 shows a distinct change of pattern for cells with 12 or more grains. These cells show labelling over the 'hot' X, which is markedly higher than for cells with less than 12 grains, indicating positive labelling. The background is about 2 grains per cell,

Table 1. GRAIN COUNT DATA OF THE 224 CELLS

Grains over autosomes + background	Cumulative No. of cells	Autosomes + background	Background	'Hot' X
0	3	0	0	0.3
1	14	1	0.6	0.7
2	41	2	1.1	0.9
3	65	3	1.5	0.9
4	94	4	2.2	0.9
5	113	5	2.2	1.3
6	129	6	2.9	1.2
7	145	7	3.2	1.1
8	155	8	4.2	0.9
9	161	9	5.5	1.8
10	164	10	5.3	2.6
11	167	11	5.0	1.3
12-13	171	12-7	1.75	9.3
14	176	14	1.0	14.5
15-20	184	17-1	2.0	8.8
21-100	205	50.9	3.2	22.6
> 100	224	242.1	5.1	40.3
0-9	161	4.28	2.12	1.01

agreeing with a random background of 2.12, the mean for cells with 9 grains or less. That the majority of the 167 cells with 11 grains or less are unlabelled is indicated by the fact that the 'hottest' in Group III has only on average about one grain, and also that about half the grains over the cells are background. However, a few of these 167 cells will nevertheless have some real label as four of them had a Group III chromosome with 5 or more grains.

Taking therefore the 161 cells with 9 grains or less as representative of the background population, a detailed analysis was made to check that these grains were randomly distributed over the cell and over the chromosomes. The mean grains per cell for this population is 4.28 (Table 1) with a mean background of 2.12, giving therefore 2.16 over the autosomes. This latter, together with 1.01 grains per cell over the 'hottest' in Group III, makes a total of 3.17 grains per cell over all the chromosomes. Since Group III contains 37.8 per cent of the chromosome material, a random distribution of grains would lead to an expected mean over Group III of 1.20. Since even

Fig. 1. Cumulative distributions of grains over the unlabelled cells. Solid lines show the Poisson distributions of 161 cells with mean grains of 4.28 and 0.72.

Fig. 2. Continuation of the cumulative distribution of the grains over the autosomes (and background) to include the labelled cells.

Fig. 3. Continuation of the cumulative distribution of grains over the 'hot' X to include the labelled cells.

with this low density, occasionally more than one chromosome in Group III will be labelled, the observed value of 1.01 over the 'hottest' is consistent with an expected value of 1.20 over the whole group. Furthermore, the distribution of grains among these cells agrees with a random distribution as is shown in Fig. 1, where the solid lines are the calculated Poisson distributions for a population of 161 unlabelled cells with a total mean count of 4.28 grains, and for a population of 161 Group III chromosomes with a mean grain count of 0.72. This latter is the mean of the smallest 161 counts over the 'hottest' chromosome in Group III; this distribution of cells being not necessarily identical with the tail of the autosome and background distribution.

(2) *Labelled cells.* From these arguments we conclude that the cumulative distributions shown in Figs. 2 and 3 are those for the labelled cells. These distributions can be interpreted by considering the consequences of the 'Colcemid' block. Without 'Colcemid', only cells which were 180 min from metaphase when the label was added will give metaphase plates. However, with 'Colcemid' added 90 min before fixation, all cells which were between 90 and 180 min before metaphase when the label was added will give metaphase plates. The proportion of these plates which show label will depend on where in the interval, 90–180 min, the DNA synthesis ends.

Since we have observed a cohort of 224 cells by the 90 min 'Colcemid' block, and since we can also assume these to be distributed uniformly in time, then these cells were coming into metaphase at $224/90 = 2.49$ cells per min. Thus, a time-scale can be put on the cumulative distributions of Figs. 2 and 3, the abscissa now becoming a linear time-scale going backwards into the *S* period. The ordinate will be proportional to the total DNA synthesis still to be completed, since the tritium label is continuously available during this incubation period, and when once incorporated in the chromosome is permanent, at least until the next cell division.

The tangents to the cumulative distribution curves, therefore, give a measure of the rate of DNA synthesis at the corresponding times. In this way the rate of DNA synthesis at the later part of the *S* period can be calculated for the 'hot' X and for the autosomes, and the results are shown in Fig. 4. Since the cumulative distributions give the total grains over the 'hot' X and over all the autosomes, the rate of increase of these grains has been divided by the length of the X chromosome, or by the total length of the autosomes, to get a specific rate of DNA synthesis, that is, a mean rate of synthesis per unit length of chromosome.

Fig. 4. The specific rate of DNA synthesis at the end of the S period

Individual cells will show a variation about the mean values of Fig. 4. One effect of this variation is to give the sharp upward tilt to the ends of curves of Figs. 2 and 3. This is due to a few cells being farther back in time in the S period than the average cell at 180 min before metaphase. From these few cells we can make a rough estimate of the average value of this time, by taking the time between the extrapolated curve and the actual curve at a grain count equal to the mean for these cells. This time corresponds to about 5–6 min for both the 'hot' X and for the autosomes.

Since the two cumulative distributions for the 'hot' X and the autosomes are independent of each other, we can examine where each individual cell occurs in the two distributions. There is a good degree of correlation and this can be expressed as the mean ranking difference of a cell in the two distributions and was calculated to be 10.8 cells. Since the cohort is progressing at 2.49 cells/min, this corresponds to $10.8/2.49 = 4.4$ min internal timing variation between the state of the 'hot' X and of the autosome DNA synthesis within a single cell.

The results obtained in these experiments with continuous labelling by tritiated thymidine indicate that the rate of DNA synthesis is constant towards the end of the

S period and then falls off sharply during the last 20 min. Our observations were limited to the last 25–30 min, therefore we cannot say how far this constant rate extends back into the S period.

Several publications have commented on the 'lateness' in labelling of the 'hot' X chromosome^{1–4,6}. This was shown by an increasing proportion of the grains located over the 'hot' X as the total grain count over the cell decreases^{1,2,6}.

The results recorded here offer a quantitative explanation of this phenomenon. The specific rate of DNA synthesis is about three times higher in the 'hot' X than in the average autosome (during the last constant part of the rates). This constant rate is maintained somewhat longer in the 'hot' X than in the average autosomes (by about 5 min). The rate in the 'hot' X then falls sharply so that both the 'hot' X and the average autosomes finally finish at about the same time, in this culture about 155 min before metaphase.

Although the two rates of synthesis end together, the ratio of the areas under the two curves in Fig. 4 is about 6, corresponding to the specific grain density of 6 for the 'hot' X reported earlier^{1,6}.

In order to single out the 'hot' X, all other chromosomes have been grouped together under the term 'average autosome'. The known differences in grain density between the various autosomes and parts of autosomes indicate that any one segment of any chromosome may have its own 'end of S' pattern. Some of these may not differ greatly from the 'hot' X, others may be greatly displaced early in time. For these reasons the curve for the average autosome might well be expected to have a more gradual ending than that of the more homogeneous 'hot' X.

It would require a very considerable amount of grain counting to provide data for any one autosome, let alone for parts of autosomes; but with suitably longer exposure of the autoradiographs it is possible to determine similar patterns at least for some of the autosomes.

SHADE TOLERANCE IN FLOWERING PLANTS

By DR. J. P. GRIME

Department of Soils and Climatology, Connecticut Agricultural Experimental Station, New Haven, Connecticut

SHADE tolerance and shade avoidance. A distinction has been drawn^{1,2} between species with seedlings which are able to penetrate rapidly through grassland shade (shade-avoiding plants) and species which are capable of surviving long periods in the dim light of the forest floor (shade-tolerant plants). Certain characteristics which facilitate rapid emergence from grassland shade have been recognized³. In this article, experimental results suggesting a physiological basis for shade tolerance are summarized.

Fungal attack and shade fatalities. Failure of seedlings in shade is almost invariably associated with fungal attack^{2–7} and often the effect of shading is to increase infection^{2,8–11}. Experimental evidence with tree seedlings² suggests that in comparison with tolerant species, shade-intolerant plants are more susceptible to infection both above and below the compensation point.

Predisposition to fungal attack. Correlations have been established between decreasing sugar content and increased susceptibility in shaded foliage^{11–13} and a causal role in resistance to infection has been ascribed to sugar content¹⁴. Consistent with this theory is a recent observation that the longevity of tree seedlings in deep shade is closely related to the quantity of material stored in the seed (Table 1).

The carbohydrate economy of the shade-tolerant seedling is therefore of interest for two reasons. If high levels of sugars are maintained in shade, continued growth may be possible; in addition we may suspect that fungal attack will be resisted.

Morphogenetic adaptation to shade. Morphogenetic changes induced by shading include increased leaf area, reduced leaf thickness and laminae inclined at right-angles to the light source^{2,15–17}. These changes appear

Table 1. NUMBER OF FATALITIES RECORDED IN SEEDLINGS OF EIGHT NORTH AMERICAN TREE SPECIES GROWN IN DEEP SHADE

	Seed reserve (mg dry wt.)	No. of fatalities
<i>Betula populifolia</i>	0.1	4.6
<i>Betula lenta</i>	0.7	5.4
<i>Rhus glabra</i>	1.5	4.8
<i>Acer rubrum</i>	7.3	3.2
<i>Larodendron tulipifera</i>	8.5	3.4
<i>Pinus strobus</i>	14.8	3.6
<i>Gleditsia triacanthos</i>	40.3	1.8
<i>Quercus rubra</i>	1,969.2	1.4

Each value tabulated is the mean number of fatalities per container over a period of twelve weeks. Initially, a single seedling was sown into each of five containers. Casualties were replaced by freshly germinated seedlings throughout the rest of the experimental period.

to be advantageous in that they increase the amount of energy intercepted by the shoot. They are not confined to shade-tolerant species¹⁸, however, although in some investigations more effective responses to shading have been observed in shade-tolerant plants¹⁷.

Metabolic adaptation to shade. Many shade-tolerant genera, for example, *Pachysandra* and *Hedera*, have thick leaves and leaf arrangements which permit considerable self-shading. Clearly this indicates that the carbohydrate solvency of shade plants may depend on conservation of energy rather than the efficiency of its capture.

Initial study of the metabolism of shade-tolerant plants has been carried out in Connecticut by measuring: (a) relative growth-rate of small plants of tolerant and intolerant species growing under full sunlight; (b) respiration in the dark in leaves of species differing widely in shade tolerance.

(a) Under the conditions of the experiment (Table 2) all the shade-tolerant species examined grew extremely slowly in comparison with the species intolerant of shade, crop plants and various weeds.

(b) In shade-tolerant species respiration rates of leaf disks in darkness were consistently lower than those measured in species from open habitats (Table 3).

From these data it would appear that shade plants have slow metabolic rates. It is not clear whether these are imposed biochemically or arise through reduced permeability of the leaf. As suggested by D. N. Moss, dark respiration may be inhibited by accumulated carbon

Table 2. RELATIVE GROWTH-RATE (MG/G/H) OF SHADE-TOLERANT SPECIES. CROP PLANTS AND SPECIES FROM UNSHADED HABITATS

Shade-tolerant species		
<i>Tsuga canadensis</i>	1.79	<i>Acer saccharum</i> 0.99

Respiration was measured as the loss in dry weight of disks from young fully expanded leaves floated on water for 12 h. Leaf samples were freshly collected from trees growing in unshaded habitats or from seedlings grown in sand culture in a greenhouse.

dioxide within the leaf and photosynthesis by slow inward diffusion of carbon dioxide. As demonstrated by Heath¹⁹, respiration may be inhibited by depletion of oxygen in leaves with tightly closed stomata. However, the alternative of control of photosynthetic and respiratory rates through common or linked slow biochemical processes is suggested by data, such as those of Thomas and Hill²⁰, which demonstrate a close correlation between rates of photosynthesis and respiration in species with high gas-exchange capacity.

Recently high-temperature optima have been observed for photosynthesis in certain sun plants^{21,22}. A high-temperature optimum for some fraction of respiration may be concomitant with this adaptation. Accordingly, in seedlings of *Paulownia tomentosa*, a shade-intolerant tree with an exceptionally high relative growth-rate in full sunlight (Table 2), leaf respiration was accelerated to a high rate over the temperature range 25°–35° C (Fig. 1). Values for a tolerant species of *Pachysandra* were comparatively low.

Fig. 1. The effect of temperature on respiration of leaf disks in darkness in *Pachysandra* (shade tolerant, ●) and *Paulownia* (intolerant, ○)

This investigation was carried out using plants grown in full sunlight. Provided the differences between tolerant and intolerant species, which have been observed in respiration rate, obtain in shade-grown plants, we may assume that depletion of carbohydrate below the compensation point will be more rapid in intolerant species. Furthermore, where intolerant species have a high Q_{10} for respiration, their compensation point will be most sensitive to changes in temperature. This was apparent in an experiment with *Paulownia*, in which a rise in temperature from 25° to 35° C caused a large depression in net photosynthesis at low light intensities (Fig. 2) and an elevation of light intensity compensation point from 300 to 1,200 ft. candles.

The contrast between tolerant and intolerant species in relative growth-rate and leaf respiration rate supports the suggestion of Went²³ that an important adaptation of shade plants has arisen through selection for slow respiration in shade with concomitant selection for slow photosynthetic rates and hence slow growth-rates in all environments. In accordance with this, photosynthetic rates of intolerant species exceed those measured in tolerant plants even when the comparison is made at low light intensities^{17,24–26}. Apparently, these high rates of photosynthesis do not confer shade tolerance. This is

Fig. 2. Net photosynthetic rate in leaf disks of *Paulownia tomentosa* incubated in a range of low light intensities at 25°C (○) and 35°C (●).

probably because, in intolerant species, they are offset by high rates of respiration and by a rapid and continuous conversion of photosynthate into plant structure.

In a wider context, it has been proposed²⁷ that the plant characteristics which lead to the failure of a genotype or species in one environment may be an indirect consequence of adaptations necessary for survival in another. Hence high respiration rate, a liability in shaded habitats, is a feature of the high metabolic rate necessary in colonization of unshaded productive environments such as aban-

doned arable fields. The distinction between tolerant and intolerant plants may, therefore, arise through a physiological dilemma; adaptation for high productivity under full sunlight involves the assumption of characteristics limiting in shade and vice versa.

THE CONCEPT OF THE 'CENTRON'

By DR. D. W. MENZIES

Department of Pathology, University of Melbourne, Australia

THIS communication proposes a structural concept which has been found useful in accounting for the behaviour of cortical follicles during antigen stimulation of rat lymph node. Such changes can be explained by supposing that the follicular lymphoid cells are grouped in relation to a pre-existent spherical stromal structure. This stromal 'centron' is considered to be constant, though its contained lymphoid population is very variable.

The case for the existence of the centron depends on consideration of the following: (a) visible changes in follicular lymphoid cells under antigen stimulation; (b) visible changes in cortical macrophage processes under antigen stimulation; (c) flow patterns of afferent lymph-borne carbon and flagellar antigen in the lymphoid cortex.

Visible changes in lymphoid cortical follicles under antigen stimulation. Within the cortex of the rat lymph node can be found a series of follicles of variable cell population, depending on the age of the animal. These age changes in follicular cytology appear to be due to the accumulation of natural antigenic stimuli, as they can be reproduced by appropriate experimental lymph-borne antigen.

In young rats (70–100 g) the follicular system is represented by a series of surface mounds. Beneath each mound can be seen in the cortex a condensation of small lymphocytes, showing in many cases the beginning of a circular edge (Fig. 1). These small lymphocyte condensations are difficult to observe in ordinary paraffin sections, as they differ from the rest of the cortical lymphocytes only in the tightness of their packing. They are best seen in unfixed frozen sections cut from a node placed in a gutter in a block of liver or other supporting material.

In older rats, these follicles are more easily defined because they differentiate into a peripheral rim of closely adherent small lymphocytes, and a central area which contains numerous primitive blast cells with prominent

Fig. 1. Lymph node cortex from 100 g rat, with subcapsular sinus macrophages marked by afferent lymph-borne carbon. Note (a) the surface mounds, (b) the spherical masses of packed lymphocytes lying below. H. and E. 5μ frozen section. (× c. 112)

nucleoli. However, this blast cell concentration can be more controllably reproduced by experimental antigen stimulation of the 70–100-g rat (0.1 c.c. TAB vaccine, Commonwealth Serum Laboratories, into the right hind footpad twice a day for 5 days).

By the fifth day of this 'mass antigen' course, examination of the right para-aortic lymph node will show in the outer cortex a series of blast cell masses, forming incomplete circles, with the outer part of their circumference obscured by packed small lymphocytes extending to the subcapsular sinus (Fig. 2). If placed more deeply, or perhaps cut obliquely, these follicles are no longer obscured by lymphocytes, and appear as a full circle (Fig. 2). In this case there is a sharp contrast between the packed blast cells of the follicle and the loose lymphocytes of the cortex outside. The smooth and well-defined edge of the blast cell mass is very obvious (Fig. 2).

Observations of serial sections of many lymph nodes under mass antigen stimulation suggest that these blast cell circles correspond to sections of a sphere 200–250 μ in diameter. Their constancy of shape and size, and the sharpness of their edge, are contrary to the idea that they are random aggregations. Instead, the appearances suggest that the blast cells fill pre-formed cortical stromal spheres, thus making them visible.

Visible changes in cortical macrophage processes under antigen stimulation. Pioneer researches of Bunting¹ and

Fig. 2. Lymph node cortex after 5 days 'mass antigen' (see text), stained by a nucleic acid method (ref. 4) showing blast cells as dark masses. Two blast cell follicles are shown. On the left, one follicle is partly obscured on its outer aspect by packed lymphocytes. On the right, another follicle is seen with a fully circular shape. Note the sharpness and smoothness of the edge of this blast cell mass. Basic fuchsin-azure B, 3 μ paraffin section. ($\times 75$)

Fig. 3. Macrophages in the lymph node cortex, the processes of which have been outlined by adherent carbon, as described in the text. The ribbon-like processes broaden into macrophage bodies containing indistinctly visible nuclei. 10 μ frozen section. ($\times 900$)

Fig. 4. Follicular mound (see left) from 100 g rat. Adherent carbon shows the general uniformity of the dendritic macrophage pattern, with no sign of follicular organization. 10 μ frozen section. ($\times c. 170$)

Fig. 5. Adherent carbon preparation of rat lymph node cortex one week after cessation of 'mass antigen'. Follicular areas of thickened dendritic macrophage processes are now easily seen. 10 μ frozen section. ($\times 75$)

others at the turn of the century have recently been reinforced by modern electron microscopy^{2,6} and the skeleton of the lymph node shown to be a protoplasmic pseudo-synctium, made up of the interlacing membranous processes of dendritic macrophages, with fibres running in extra-cytoplasmic tunnels and providing occasional reinforcement.

These stromal macrophage extensions can be outlined by the application of colloidal carbon. 10 μ frozen unfixed sections of lymph node, dried on the slide at room temperature for 6–8 h, are flooded with 'Pelikan' indian ink (Günther Wagner C11/1431a), for 10 sec and washed with a 4 per cent aqueous dilution of the same ink. This dilution is finally used as a mounting medium under a coverslip.

The carbon adheres selectively to the bodies and processes of macrophages, leaving lymphoid cells almost completely unmarked (Fig. 3). Observation has to be speedy, as the carbon particles dislocate from the macrophages after 15–20 min. Washing the preparation with water, as in any attempt to counterstain, results in the same dislocation. Drying may have the same effect. Before or after carbon adhesion, fixation by such agents as alcohol, formalin, or mercuric chloride abolishes the specific localization.

The method shows lymph node stroma as a network of narrow ribbons which broaden out at intervals into macrophage bodies with recognizable, but indistinctly visible, negatively staining nuclei (Fig. 3).

In the 80–100-g rat, the follicular mounds exhibit no distinctive stromal morphology in the sites where primary follicular lymphocyte condensations could normally be

Fig. 6. Rat lymph node cortex, 2.5 h after carbon injection of corresponding footpad. Note how the carbon has penetrated the inner wall of the heavily marked subcapsular sinus (see left) and is spreading through the cortex along the arms of dendritic macrophages. Carbon does not penetrate into the circularly outlined primary follicle. 10μ frozen section. ($\times c. 170$)

expected (Fig. 4). Even under mass antigen stimulation, there is no stromal counterpart of the blast cell circles which appear so early and consistently under these conditions. About the fifth and final day of the antigen course, and especially during the week following, follicular organization does appear, in the form of circular clusters of thickened macrophage processes (Fig. 5). It must be emphasized that this is a late event, only produced by intense and prolonged antigen stimulation.

Flow patterns of afferent lymph-borne carbon and flagellar antigen in the lymphoid cortex. Stromal follicles can thus be produced by antigen, but the evidence so far does not prove whether such follicles constitute a pre-formed structure in the unstimulated cortex. Studies of the early localization of lymph-borne carbon and flagellar antigen do, however, provide pointers in this direction.

0.2 c.c. 'Pelikan' indian ink is injected into the right hind footpad of the 80–100 g rat which has received no previous antigen. Two and a half hours later, the right para-aortic node is cut into frozen sections. These show the whole sinus system of the node outlined in black, and some direct penetration of the cortex by the carbon through the inner wall of the subcapsular sinus. Both these observations agree with Drinker *et al.*³

As the carbon penetrates the outer cortex, it outlines the processes of dendritic macrophages. It also negatively outlines circular follicular areas beneath the subcapsular

sinus (Fig. 6). Nuclear counterstaining is possible, as carbon, adherent to dendritic macrophages *in vivo*, resists subsequent water dislocation in frozen sections. Such counterstaining shows that the area of minimum penetration corresponds with primary lymphocytic follicles.

Further information has been supplied by Nossal *et al.*⁶, who have recently investigated the cortical distribution of afferent lymph-borne flagellar antigen marked by radio-iodine. Within 24 h of footpad injection of primary antigen, the corresponding popliteal lymph node shows circular or ovoid areas of tagged protein, which in terms of their contained lymphoid population may be indistinguishable from the rest of the cortex. At a later stage, blast cells are seen to appear and become numerous in each protein area, a classical lymphoid germinal centre being the end product.

Radio-iodine does not give sufficiently sharp localization of the actual cells involved in this protein localization. However, fluorescent antigen marking⁵ has since shown that these cortical areas are composed of circular clusters of protein-marked dendritic macrophages identical in morphology to the antigen-induced follicles demonstrated by carbon adhesion, and presumably representing the same structure.

Conclusion. The combined weight of this evidence supports the idea of a pre-existent stromal macrophage centre, with a contained lymphoid population varying from small lymphocytes to blast cells according to the conditions of antigen stimulation. The problem is how to define this structure anatomically.

The difficulty is that the macrophages inside this structure do not appear to differ morphologically from the cortical macrophages outside, nor are they arranged in any constant or obvious way as a boundary structure.

Yet such a boundary seems very likely, whether in terms of the processes of macrophages, or in terms of some type of basement membrane. If such a barrier does exist, particles carried by lymph through the cortex³ would be deflected from the outside of the stromal sphere (short-term carbon) or concentrated in the inside (antigenic protein), depending on complex physical factors such as barrier porosity, speed of lymph flow, and size of the particle concerned.

IMMUNOLOGY OF THE MOUSE MAMMARY TUMOUR VIRUS (MTV): A QUALITATIVE *in vitro* ASSAY FOR MTV

By PHYLLIS B. BLAIR

Department of Bacteriology and Immunology and Cancer Research Genetics Laboratory,
University of California, Berkeley

EXPERIMENTAL investigations of MTV are considerably hampered by the absence of a short-term *in vitro* assay. The conventional assay for the presence of infectious MTV has been the measurement of tumour development in susceptible test mice injected while young with extracts of infected mammary tissues or of milk¹. This test requires 1–2 years for its completion. This time-interval has been shortened in a recently developed technique in which the end-point is the development of hyperplastic alveolar nodules in the mammary glands of test mice², but even this assay requires 4–5 months.

It is feasible to shorten the assay time still further by the development of techniques which measure the antigenicity rather than the biological activity of MTV. A number of attempts to demonstrate MTV by standard immunological techniques have been reported, using antisera obtained from rabbits or guinea-pigs immunized with MTV-containing tissue extracts or milk. It is well established that such antisera are capable of neutralizing the biological activity of MTV³. *In vitro* techniques have included passive haemagglutination, precipitin, and complement-fixation tests⁴. Precipitation reactions specific

for MTV in immunodiffusion agar plates have also been reported⁵.

This article reports the development of the immunodiffusion technique as a qualitative assay for the presence of MTV. In its present form, the assay requires six weeks for its completion, including the time necessary for the preparation of the rabbit antiserum.

The methods used in the preparation of the tissue extracts and of the rabbit antisera were similar to those previously reported for work on the neutralization of MTV infectivity¹. The tissues were homogenized in saline and clarified by a 30-min centrifugation at 1,500*g*. The supernatant was then centrifuged at 30,000*g* for 90 min. The resulting pellet was resuspended in saline, so that 1 ml. saline contained the material obtained from either 1 or 2 g. wet weight, of tissue. This suspension was clarified by centrifugation at 1,500*g* for 15 min, and the supernatant was frozen at 4° C until needed. Material prepared by this method was used as the antigen preparation for injection into rabbits, for absorption of the rabbit antisera, and in the immunodiffusion plates.

Young adult female New Zealand rabbits were used for the production of antiserum. Each rabbit received a total of tissue extract equivalent to 2.5–4.0 g of original tissue, in 4 weekly intramuscular injections, and was bled one week after the final injection. The resulting sera were frozen at 4° C until used. The antiserum from each rabbit was stored and used separately. Each antiserum was used undiluted in the plates except in the absorption experiments. Antisera were obtained from rabbits which had been immunized with one of the following tissues:

(A) Tissues obtained from isogenic *BALB/cCrgl* and *BALB/cfC3H/Crgl* mice.

(1) Lactating mammary glands from *BALB/c* females. These mice are not infected with MTV, and antisera from rabbits immunized with preparations of this material do not neutralize the biological activity of MTV¹.

(2) Transplant generations 3 through 7 of a *BALB/c* mammary tumour which arose spontaneously in a 21-month-old *BALB/c* female. No virus particles were observed when samples of the tumour were examined in the electron microscope⁶.

(3) Lactating mammary glands from *BALB/cfC3H* females. This strain, in its 3rd to 5th generations, was started by fostering new-born *BALB/c* mice on *C3H/Crgl* lactating females, and using the babies when adult as generation 1 of the strain. Thus, these mice are isogenic with *BALB/c* mice, but are infected with MTV.

(4) Transplanted outgrowths of hyperplastic alveolar nodules and transplanted mammary tumours obtained from *BALB/cfC3H* females. These tissues contain virus particles as observed in the electron microscope and also biologically active MTV.

(B) Tissue obtained from a strain of mice which is not infected with MTV.

(1) Lactating mammary glands from *C57BL/Crgl* females.

(C) Tissues obtained from strains of mice which are infected with MTV.

(1) Lactating mammary glands from *C3H* females.

(2) Spontaneous and transplanted mammary tumours from *C3H* females.

(3) Spontaneous mammary tumours from *RIII/Crgl* females.

(4) Spontaneous mammary tumours from *A/Crgl* females.

(5) Spontaneous mammary tumours from *DBA/2Crgl* females.

The tissue preparations routinely used as antigen in the immunodiffusion plates were obtained from *BALB/cfC3H* spontaneous and transplanted mammary tumours. In some experiments, tissue preparations of *DBA/2* mammary tumours were also used as the antigen. Preparations of mammary tumours from the other strains of mice (*C3H*,

RIII and *A*) have so far not been used successfully as antigens in the immunodiffusion plates.

In absorption experiments, the various antisera were absorbed with MTV-free or MTV-containing tissue preparations. The antisera were combined with the tissue extracts and then maintained at room temperature for 2 with occasional manual agitation. The mixtures were clarified by centrifugation at 1,500*g* for 15 min, and the serum-containing supernatants were then added to the immunodiffusion plates.

The agar plates were prepared with 0.6 per cent Noble agar, 0.85 per cent sodium chloride, and 1:10,000 merthiolate in distilled water, at pH 7. Wells were cut with a 6-mm diameter cork borer in the pattern illustrated in Fig. 1. The distance from the centre of the antigen well to the centre of the antiserum well was 11 mm. Six antisera could be tested on each plate, and the experiments were designed so that the plates contained both positive and a negative control. The standard antigen preparation was placed in the two centre wells one day before the antisera were added to the other wells. The centre wells were refilled with saline once daily for two days after the introduction of the antigen preparation. The plates were maintained at room temperature. Precipitate lines were visible within a few days, but the plates were routinely examined for a period of two weeks.

Each of the antisera already described here was tested against the standard MTV-containing antigen preparation in several separate experiments. In most experiments no absorption of antiserum was carried out, and each antiserum produced several precipitate lines with the antigen. This is an expected result, since the standard antigen preparation contains not only MTV or MTV-induced antigen but also normal tissue antigens. The precipitate line characteristic of MTV was initially found by a comparison of the precipitate lines made by antisera obtained from rabbits immunized with *BALB/cfC3H* tissues (which contain MTV) with those made by antisera obtained from rabbits immunized with the isogenic but virus-free *BALB/c* tissues. Precipitate lines specific for

Fig. 1. Immunodiffusion of rabbit antisera and extracts of *BALB/cfC3H* mammary tumours. The three top wells were filled with, left to right, (1) rabbit antiserum against *BALB/c* lactating gland, (2) rabbit antiserum against *BALB/cfC3H* mammary tumour, and (3) rabbit antiserum against *BALB/c* lactating gland. The two centre antigen wells were filled with the standard antigen preparation of *BALB/cfC3H* mammary tumour. The three bottom wells were filled with, left to right, (1) rabbit antiserum against *C3H* mammary tumour, (2) rabbit antiserum against *DBA/2* mammary tumour, and (3) rabbit antiserum against *C3H* mammary tumour. The characteristic precipitate lines (indicated by the arrow) are found near the antigen wells wherever the advancing antiserum contained antibodies against MTV, but not in the two areas where the advancing antisera were from rabbits immunized with virus-free *BALB/c* tissues ($\times 1.3$).

sue antigens were observed in the vicinity of the antigen wells; the precipitate line characteristic of MTV was found near the antigen wells (Fig. 1). The MTV specificity of the line was tested by using antisera from rabbits immunized with tissues from other strains of mice known to contain MTV. The specificity was further tested by using antisera which had been absorbed with virus-free tissue preparations; the absorbed antisera produced only the line characteristic of MTV in the immunodiffusion plates.

As recorded in Table 1, all the antisera from rabbits immunized with normal or neoplastic tissues containing MTV (obtained from 5 different strains of mice) produced a characteristic precipitate line. On the other hand, none of the antisera from rabbits immunized with BALB/c C57BL tissues (which do not contain MTV) produced this line.

Further, in the absorption experiments completed so far (Table 2), extracts of tissues which do not contain MTV are not capable of absorbing the antibodies responsible for the formation of the characteristic precipitate line. In contrast, the antibodies were removed by absorption with preparations of either normal or neoplastic tissues which do contain MTV.

The fact that antisera from rabbits immunized with tissues obtained from a variety of mouse strains infected with MTV all produced the characteristic precipitate line in this test system indicates that the MTVs carried by different strains of mice contain at least one antigen in common. This is in agreement with the results of previous neutralization studies, in which antisera from rabbits immunized with the MTV from one strain of mice were capable of neutralizing the biological activity of the MTV from other strains of mice^{1,7}. Based on this common antigenicity, the immunodiffusion technique has a potential usefulness as an assay system for the MTV from any strain.

Not only similarities but also differences in biological activity⁸, morphology⁹, and antigenicity¹⁰ of the MTVs from various strains of mice have been reported. The scope of such investigations has been limited by the cumbersome *in vivo* assay for the presence of infectious MTV. Moreover, there frequently is little correlation between the presence of the type B virus particles considered to be MTV and the presence of biologically active MTV, and various explanations for this lack of correlation have been proposed¹¹. An assay method which is based on the presence of a common MTV antigenicity, rather

than on biological activity, can be expected to resolve some of these differences in interpretation.

The antigenic component responsible for the production of the characteristic precipitate in the immunodiffusion assay appears to be the intact type B virus particle¹². This particulate antigenic component can be sedimented by centrifugation at 30,000g for 1.5 h or less. The MTV-associated antigen found by Lezhneva³ in the lactating mammary glands of FIII mice was a much smaller component. It remained in the supernatant even after centrifugation at 100,000g for 1.5 h. These two MTV-associated components may represent the two sizes of infective MTV reported by Moore¹³. It is also quite possible that the smaller component may represent fragments of the type B particle, or a virus-induced antigen.

As reported here, all MTV-containing antigen preparations tested were successfully used for the production of antisera in rabbits which then produced the characteristic precipitate line when tested against the standard MTV-containing antigen preparation in the immunodiffusion plates. However, some of the same preparations did not produce the characteristic precipitate line when they were used as antigens in the plates, and tested against standard antisera. This is probably related to the concentration of MTV antigen in these preparations. The concentration of the type B virus particle varies considerably in MTV-containing tissues from different sources⁹. As expected, MTV-free BALB/c tissue preparations cannot be used as antigen in immunodiffusion.

The qualitative *in vitro* test described herein is, nevertheless, ideally suited to indicate the presence or absence of MTV in tissues, by using the suspect tissues as antigen for immunization of rabbits and then testing these antisera against standard MTV-containing preparations in the immunodiffusion plates. The assay can also be developed to provide data on the relative amounts of MTV-related antigen in various tissues, by means of absorption of standard antisera with the different tissue preparations. Antigenic differences between the MTVs carried by different strains can also be examined, again utilizing absorption experiments. That such experiments may be subject to quantitation is indicated by work with other viruses¹⁴. Quantitative absorption experiments designed to investigate these possibilities are currently in progress.

INCREASED SENSITIVITY OF *IN VITRO* MURINE LEUKAEMIA CELLS TO FRACTIONATED X-RAYS AND FAST NEUTRONS

By DR. WILLIAM L. CALDWELL and PROF. LEONARD F. LAMERTON
Department of Biophysics, Institute of Cancer Research (Surrey Branch), Sutton, Surrey

AND

DR. DAVID K. BEWLEY

Medical Research Council Cyclotron Unit, Hammersmith Hospital, London, W.12

FOLLOWING the original report of Elkind and Sutton¹, the variation with time in radiosensitivity after a single dose of radiation has been studied for a number of different cell systems. They have all shown a similar pattern of change, but with differences in the degree of variation. In no case, however, has the net effect of a given dose delivered in two fractions been greater than that of a similar undivided exposure.

In this article, investigations are reported using a mammalian cell suspension in which it has been found that the radiosensitivity increases above normal following an initial dose of radiation. The data are described and discussed in relation to possible mechanisms operating.

Murine leukaemia cells growing *in vitro* in suspension were used for the investigations. These were made available by Dr. Peter Alexander of the Chester Beatty Research Institute². The cells were grown at 37° C in a specially prepared, balanced medium³, and under control conditions have a doubling time of 9–10 h. The cells were irradiated in polypropylene tubes at 37° C with 230 kVp. X-rays (half value layer, 1.5 mm copper) at a dose rate of 41 rads/min, or with fast neutrons having a mean energy of 6 MeV at about 50 rads/min. The dose-survival curves were obtained by backward extrapolation of growth curves, following varying doses of radiation. Since the growth curves were parallel for all doses approximately 48–60 h after radiation, extrapolation gave the surviving fraction after a correction was made for mitotic delay⁴. This correction is not large, and resulted in an uncorrected D_{37} of 55 rads becoming 62 rads on correction.

In order to evaluate the survival kinetics of the cells in the divided dose experiments, cell survival 100 h after the initial exposure was measured. Survival at this time can be considered a measure of reproductive integrity since, even accounting for mitotic delay, 100 h is equivalent to approximately 10 cell cycles. Radiation doses totalling 200 rads of X-rays or 80 rads of neutrons were used for all experiments. Counts of viable cells were made in standard haemocytometers using phase-contrast microscopy.

Fig. 1 shows dose survival curves for X-rays and fast neutrons respectively. The X-ray curve clearly has no very substantial shoulder, but the scatter of the experimental points does not allow the degree of shoulder to be determined with any precision. Alexander and Mikulski², using the same cells with the same medium, observed a slight shoulder, but a correction for mitotic delay would very largely eliminate it. With the neutrons there would appear to be very little, if any, shoulder. With neutrons the D_{37} is 27 rads; this implies a relative biological effectiveness (RBE) of 2.3, when compared with the D_{37} of 62 rads for 250 kVp. X-rays.

Fig. 2 shows the mitotic delay induced by a range of doses of X-rays. Preliminary measurements have also been made with neutrons, for which the response shows a similar pattern of change with time as for X-rays, with an RBE of 2–2.5.

Fig. 3 shows the relative survival after a pair of equal exposures for varying intervals of time between them. It can be seen that with both X-rays and neutrons there is a brief period of decreased sensitivity to a second exposure, followed by an interval (from about the fourth to tenth hour) in which sensitivity is actually increased

above normal. The form of the curve is similar for the types of radiation with smaller variation in the case of neutrons. With X-rays, and an interval of about 6 h between exposures, survival is approximately 50 per cent of that for cells exposed to the same total amount of radiation at one time, and with neutrons about 70 per cent.

Using X-rays, an investigation was also made of survival when the time-interval between radiation fractions was kept constant at 5 h and the exposure fractions varied. The relative survival curve is given in Fig. 4, and it shows an increased sensitivity for all tested fractionations with the maximum effect when the initial dose was 180 rads and the second dose 180 rads.

Fig. 1. Dose-survival curves for X-rays and neutrons. ○, X-rays; ×, neutrons.

Fig. 2. Mitotic index curves following different doses of X-radiation (rads). □, 20; ○, 25; △, 50; +, 100; ●, 200.

Fig. 3. Cell survival following a pair of equal exposures given at various intervals. Two doses each of 100 rads given for X-rays, and two doses each of 40 rads for neutrons. Points represent results from two separate experiments. Δ , \square , Neutrons (2×40 rads); \times , \circ , X-rays (2×100 rads)

Fig. 4. Cell survival under X-rays following different fractionation schemes at a constant time interval of 5 h, compared with survival following a single exposure of 200 rads. Points represent results from two separate experiments

The two features of particular interest in these results are: (1) that the sensitivity after an initial conditioning dose is actually increased above normal; (2) that with an interval of 5 h between exposures the effect of a total dose of 200 rads is greater when the smaller fraction is given first (the maximum effect on survival being achieved with an initial dose of 20 rads).

In other cell systems in which the response to divided doses has been reported, the increase in sensitivity following the initial decrease has been relative only, sensitivity to the second exposure approaching, but not exceeding, control-levels. However, the dose-survival curves for these systems all have a substantial initial shoulder and therefore it is possible that at least part of the explanation for the difference lies in the lack of a significant initial shoulder in the survival curve of the cells used in the present study.

Elkind⁵ originally concluded that recovery after an initial exposure was associated with reconstruction of the shoulder of the dose-survival curve; that is, with return of the extrapolation number, changed by the conditioning exposure, to its original value. Afterwards, the work of Terasima and Tolmach⁶ gave support to Kallman's hypothesis⁷ that the change in sensitivity was related to a shift in the proportion of cells in different compartments of the mitotic cycle characterized by different sensitivities. Recently, synchronization investigations^{8,9} provide data supporting the model of recovery kinetics for dose fractionation experiments which had been suggested by Elkind,

Sutton and Moses¹⁰; that is, that the initial decrease in sensitivity following a conditioning exposure results from recovery of sub-lethal damage (reconstitution of the shoulder of the dose-survival curve) while the subsequent relative increase in sensitivity is the result of phasing of cells within sensitive phases of the mitotic cycle.

At the same time one must recognize that other processes may also be operative. It is of interest that Beer *et al.*¹¹ and Lett *et al.*¹² have shown that various factors connected with culture conditions can alter the radio-sensitivity of these leukaemia cells, neither D_{37} nor the extrapolation number remaining constant. It is possible that when these cells are given two radiation exposures, the first exposure may modify the growth conditions so as to alter the response to the second exposure.

If the difference between the present results and those of Till and McCulloch¹³, for example, were a consequence of the initial shoulder, then subtraction of the two curves should show the effect of the shoulder. Fig. 5 shows the results of this operation. Making allowance for difference in time intervals (as indicated), subtraction of the leukaemia curve from that obtained by Till and McCulloch for mouse bone marrow cells yields the curve (c), which could possibly represent the 'shoulder' effect. On this basis, the variation in sensitivity found for the leukaemia cells would have to be due to variation in radiation response with cell phase, associated with partial synchronization of the cells following irradiation, or to an entirely new process not so far postulated.

One conclusion that can be drawn from the mitotic index data of Fig. 2 is that the variation of sensitivity following a conditioning dose is not the result of an altered sensitivity during mitosis. So far as phasing effects are concerned, interpretation of the mitotic data is not straightforward since, particularly with the higher doses, many of the cells being counted, including those in mitosis, are 'doomed' (destined to die in a future division cycle). Phasing of the viable cells might be obscured by the presence of 'doomed' cells, in which case, with passage of time, peaks of mitotic activity of viable cells should be detectable, as the 'doomed' cell population diminished, provided the variation in post-irradiation cell-cycle times was not sufficient to obscure such peaks. Preliminary explorations for such peaks in leukaemia cells have been fruitless.

The significance of cell phasing in divided-dose survival kinetics in any cell system still remains to be clarified. Experimental investigations have given very diverse results concerning the change of sensitivity with phase of the cell cycle. A further difficulty in explaining the results by a simple phasing effect is that Whitmore⁸ found, in

Fig. 5. Comparison of a typical curve (a) of change in sensitivity to a second exposure following a conditioning exposure (ref. 13) with the curve (b) obtained for leukaemia cells. Differences in time between fractions for the two curves are as indicated. Curve (c) results from a subtraction of curves (a) and (b)

his synchronized *L* cells, an initial upswing in the 'recovery curve' following a conditioning exposure during all phases of the mitotic cycle. Apparently unrelated to phasing, this initial upswing was thought to be primarily the result of recovery of that sub-lethal damage which gives rise to the shoulder of the curve. However, since this upswing is also seen in the leukaemia cells with both X-rays and neutrons where the shoulder is either small or absent (Fig. 3), it seems necessary to postulate some other process.

There is, however, another possible interpretation of the results which does not require the assumption of a new process of recovery. If the sensitivity varies over the various phases of the cell cycle, the survival curve for the leukaemia cells cannot be a true exponential, but must represent the combined survival of various fractions. It is possible that one or more of these fractions has an initial shoulder. As a simple model it can be shown, for example, that if the cells consisted of 60 per cent with a D_{37} of 62 rads and an extrapolation number of 1.67 and 40 per cent with a D_{37} of 20 rads and an extrapolation number of 1.00, the combined curve would be practically indistinguishable from an experimental curve with a D_{37} of 62 rads. In this case the component with a shoulder could be responsible for the increased survival at 1 h and the subsequent swing could be due to phasing. The finding that the effect of the split dose was less with the larger fraction given first would be explained if the selective killing by the conditioning exposure were such that, at 5 h, a greater proportion of surviving cells were concentrated in their sensitive phase after a small dose than after a large dose. The maximal effect found with about 20 rads as the initial exposure presumably represents the optimal combination of 'sensitization' and size of the second exposure.

To decide whether the foregoing hypothesis is correct, or whether some other mechanism, such as modification of actual repair processes, is operating requires investigation of the effect of different dose fractions at different

time-intervals and of the response of synchronized populations of the cells.

Studies with high LET radiation could presumably help a great deal in disentangling the various mechanisms operating. Radiation of sufficiently high LET might give a true exponential survival curve instead of synthetic one, and in these circumstances it is generally assumed that no recovery would be expected¹⁴. Fast neutrons give rise to a wide spectrum of LET, and the reduced variation in sensitivity found with neutrons, compared with the lower LET X-rays, is consistent with this idea. On the other hand, the possibility must not be ignored that some recovery processes may operate even with high LET radiation.

We thank Mrs. D. Courtenay, Mr. P. Coultas and I. N. M. Blackett for their advice, and Dr. S. Field and Mr. Parnell for help in the neutron experiments, and Prof. D. W. Smithers, director of the Radiotherapy Department, for his interest in this investigation. One of us (W. L. C.) is a Special Fellow of the National Cancer Institute, U.S. Public Health Service, on leave from the Department of Radiology, Stanford University School of Medicine, Palo Alto, California.

EFFECT OF GASTRIN ON ISOLATED SMOOTH MUSCLE PREPARATIONS

By DR. A. BENNETT

Department of Surgery, King's College Hospital Medical School, Denmark Hill, London, S.E.5

EDKINS^{1,2} found that intravenous injections of crude aqueous antral extracts into anaesthetized cats stimulated the secretion of acid gastric juice. Since then many workers have studied the secretory activity of antral extracts. Blair *et al.*³ noticed that the intravenous injection of an antral extract into anaesthetized cats not only stimulated gastric secretion, but also increased the tone of the stomach and small intestine. Gregory and Tracy^{4,5} extracted hog antra and obtained two pure, almost identical, peptides which they called gastrins I and II. These stimulated gastric secretion and also contracted the stomach and jejunum in the dog. Very little is known about this stimulation of gastro-intestinal motility and the present experiments were carried out to examine the effect of pure gastrin II on guinea-pig and rat smooth muscle preparations.

Rat colon and rat uterus preparations were suspended in an organ bath containing de Jalon's fluid at 28° C bubbled with oxygen. All the other smooth muscle preparations were suspended in Krebs's solution at 37° C bubbled with 95 per cent oxygen and 5 per cent carbon dioxide. The responses of the tissues were recorded on a smoked drum by a light frontal writing lever (magnification $\times 12$). In some experiments guinea-pig ileum preparations were stimulated transmurally⁶ through coaxial electrodes. Drugs used were acetylcholine per-

chlorate, cocaine hydrochloride, dimethylphenylpiperazinium iodide (DMPP), hexamethonium bromide, histamin acid phosphate, 5-hydroxytryptamine creatinine sulphate (5-HT), (-) hyosine hydrobromide, gastrin II, mepyramine maleate, methysergide, morphine sulphate and physostigmine sulphate. The concentrations of cocaine hydrochloride, DMPP and methysergide are expressed as the salt. Other concentrations are in terms of base.

Gastrin II (1–2 $\mu\text{g}/\text{ml}$.) caused small contractions of the rat fundus strip preparation⁷, the rat duodenum and the rat colon. Guinea-pig sacculus rotundus and a strip of antrum and body cut from the rat stomach contracted feebly, and the rat uterus not at all in the presence of 1–4 $\mu\text{g}/\text{ml}$ of gastrin. The most responsive preparation encountered was guinea-pig ileum which usually contracted well in response to 0.1–4 $\mu\text{g}/\text{ml}$ of gastrin. Misiewicz and Waller (personal communication) found that 0.5–1 $\mu\text{g}/\text{ml}$ of gastrin I contracted 5 of 11 strips of human isolated stomach and that tachyphylaxis occurred. The analysis of the action of gastrin described here was carried out on the guinea-pig isolated ileum preparation.

Gastrin II produced a contraction of guinea-pig ileum which was rapid in onset and which quickly reached a peak. Sometimes the contraction was maintained, but often the tissue partially relaxed while gastrin was still

the bath. A second dose added soon after the first had been washed out produced a smaller effect. In order to prevent this tachyphylaxis, gastrin was administered at intervals of approximately 15 min. Mepyramine (100 ng/ml.) completely blocked the responses to histamine; it had no effect on the responses to gastrin in 3 experiments, but in another experiment 10 ng/ml. of mepyramine slightly reduced the effect of gastrin. The H_1 antagonist methysergide (which only partially antagonizes 5-HT on the guinea-pig ileum⁸) had no effect on the responses to gastrin in 3 experiments (methysergide 100 ng/ml.). In another 4 experiments methysergide (10 ng/ml.) reduced the contraction produced by gastrin, since the responses to acetylcholine were also a little reduced in 3 of these 4 experiments the antagonism was probably non-specific.

In each of 6 experiments hexamethonium (10 μ g/ml.) almost completely abolished the response of the ileum to DMPP but had no effect on the response to gastrin (Fig. 1). Hyoscine (2–200 ng/ml.), however, completely abolished the contraction produced by acetylcholine in 3 experiments and either completely abolished the response to gastrin (7 experiments) or reduced its effect (3 experiments; hyoscine 4 ng/ml.). When the hyoscine was washed out the effects of acetylcholine and gastrin were restored together (Fig. 2). During a hyoscine block, additions to the bath of 20–40 ng/ml. of eserine (3 experiments) restored or even potentiated the responses to acetylcholine and gastrin (Fig. 2). Eserine (20–100 ng/ml.) added to the bath in the absence of hyoscine potentiated responses to acetylcholine and gastrin equally in 4 experiments, and potentiated gastrin more than acetylcholine in 2 experiments.

These results suggest that gastrin acts either on acetylcholine receptors in the muscle or, more likely, on the postganglionic parasympathetic nerves at a site not blocked by hexamethonium to cause the release of acetylcholine. These possibilities were tested by using: (a) atropine to prevent the release of acetylcholine⁹; (b) anoxia to prevent nervous conduction⁸; (c) cocaine in an attempt to anaesthetize the nervous tissue in the ileum.

The responses to gastrin and DMPP were reduced in 2 experiments or almost abolished (2 experiments, see Fig. 3) by morphine (10–100 ng/ml.). The responses to acetylcholine were slightly depressed in 3 of the 5 experiments, and the responses to transmural stimulation were reduced in each of 3 experiments in which coaxial stimulation was used.

The effects of anoxia on responses to gastrin were studied in 4 experiments by replacing the oxygen/carbon dioxide mixture with nitrogen or with a nitrogen/carbon dioxide mixture. Anoxia abolished the effects of transmural stimulation and almost completely prevented the responses to gastrin and DMPP (Fig. 4). The effects of acetylcholine and histamine were reduced to a much less extent and the responses of the ileum to histamine and acetylcholine approximated their pre-anoxia effects when the doses of the agonists were doubled. On the other hand, increasing the doses of gastrin and DMPP 7–10 times produced only moderate or small contractions. These results indicate that gastrin acts on nervous tissue, but since it produced a small effect on the anoxic ileum it is possible that gastrin also has a small direct effect on muscle cells. In each of 6 experiments cocaine hydrochloride (10–25 μ g/ml.) almost completely blocked the effect of DMPP. In 2 of these experiments the responses to gastrin were unaffected, but in 3 experiments the effect of gastrin was slightly reduced (Fig. 5) and in one instance it was almost completely abolished. The effect of cocaine (20 μ g/ml.) on the response of the ileum to transmural stimulation of the nerves by single shocks (6/min, 0.5 msec and 3 V) was examined in 3 of these 6 experiments. Surprisingly, the contractions were only slightly reduced in 2 experiments and were unaffected in the other, thus indicating that cocaine in this concentration has little or no effect on transmission in postganglionic parasympathetic nerve endings. The finding that cocaine always abolished the effect of DMPP, but only sometimes reduced the effect of gastrin, supports the evidence obtained with hexamethonium that DMPP and gastrin act at different sites. The variation in the effect of cocaine on the response to gastrin is apparently explained by the finding that cocaine only sometimes reduced the effect of electrical stimulation, presumably by partial anaesthesia of the nerves.

All these experiments indicate that gastrin acts on the postganglionic parasympathetic nerves, and suggest that in the guinea-pig ileum the contraction produced by gastrin is caused by the release of acetylcholine. Such a view is consistent with the results of Gregory and Tracy⁵ that atropine reduces the motor effect of gastrin on the stomach and jejunum of the dog. It is of great interest that atropine also inhibits the stimulation of gastric secretion by gastrin in the dog^{10–12} and in man¹². It may follow that gastrin stimulates secretion by acting on nerves to release acetylcholine.

Fig. 1. The lack of effect of hexamethonium on the response of guinea-pig ileum to gastrin. Hexamethonium inhibited the response to DMPP but did not alter the response to gastrin. The numbers by the agonist drugs represent drug concentrations in ng/ml.

Fig. 2. The effects of hyoscine and of eserine on the response to gastrin. Hyoscine abolished the effects of acetylcholine and gastrin. When the hyoscine was washed out the responses to acetylcholine and gastrin started to return. After the addition of eserine both gastrin and acetylcholine were greatly potentiated. The numbers by the drugs represent concentrations in ng/ml.

Fig. 3. The effect of morphine on the response to gastrin. Morphine greatly reduced the effects of gastrin, DMPP and transmural stimulation. The numbers represent drug concentrations in ng/ml. During transmural stimulation (3 V, 0.5 msec, 4 shocks/min) the drum speed was reduced to one-eighth.

Fig. 4. The effect of anoxia on the response to gastrin. Anoxia completely abolished the effect of transmural stimulation at 3 V, 1 msec, 6 shocks/min; 3 V, 1 msec, 5 shocks/sec (T, 3 volts) and 60 V, 1 msec, 5 shocks/sec (T, 60 volts). Anoxia slightly reduced the responses to acetylcholine and histamine but greatly reduced those to gastrin and DMPP. The responses to gastrin and DMPP approached their pre-anoxia levels when the doses were increased from 750 ng/ml. to 5,000 ng/ml.

Fig. 5. The effect of cocaine on the response to gastrin. Cocaine almost abolished the response to DMPP but only slightly reduced the effects of transmural stimulation and of gastrin. The numbers by the agonists represent the drug concentrations in ng/ml. During transmural stimulation (3 V, 0.5 msec, 6 shocks/min) the drum speed was reduced to one-eighth.

I thank Prof. R. A. Gregory and Dr. B. A. L. Hurn of the Wellcome Research Laboratories for samples of gastrin II, and Dr. J. R. Vane for his advice.

LETTERS TO THE EDITOR

PHYSICS

Structural Basis of Neutron and Proton Magic Numbers in Atomic Nuclei

In 1933 Elsasser¹ pointed out that some of the properties of atomic nuclei correspond to greater stability for certain numbers of neutrons and protons (given the name magic numbers) than for other numbers; the magic numbers for both N (neutron number) and Z (proton number) are 2, 8, 20, 50, 82 and 126. (Less-pronounced effects are observed also for N or Z equal to 6, 14, 28, 40, and some larger numbers. The set of magic numbers is often assumed to include 28.)

The magic numbers do not have the values $(2n^2)$ for completed shells of fermions (with all states with total quantum number n , azimuthal quantum number $l \leq n-1$, occupied by pairs), which are 2, 8, 18, 32, 50, ..., nor the values for certain shells and sub-shells that lead to maximum stability for electrons in atoms, which are 2, 10, 18, 36, 54 and 86.

It was discovered by Mayer² and by Haxel, Jensen and Suess³ that the magic numbers can be accounted for by use of the sub-sub-shells corresponding to spin-orbit coupling of individual nucleons; that is, to the values of $j = l + 1/2$ and $l - 1/2$ for the two sub-sub-shells of each sub-shell. For example, they⁴ assign to N or $Z = 50$ the configuration $(1s1/2)^2(1p3/2)^4(1p1/2)^2(1d5/2)^6(2s1/2)^2(1d3/2)^4(1f7/2)^8(2p3/2)^4(1f5/2)^6(2p1/2)^2(1g9/2)^{10}$, which may be written more briefly as $1s^21p^61d^{10}2s^22p^61f^{14}(1g9/2)^{10}$.

The evidence for spin-orbit coupling and for the Mayer-Jensen shell model is convincing. It is, however, difficult to understand, on the basis of their arguments, why the six magic numbers should be outstanding among the many numbers corresponding to the completion of spin-orbit sub-sub-shells, which (for the Mayer-Jensen sequence⁴ of energy-levels) are 2, 6, 8, 14, 16, 20, 28, 32, 38, 40, 50, 56, 64, 68, 70, 82, 92, 100, 106, 110, 112, 126, 136, 142,

In the course of developing a theory of nuclear structure based on the assumption of closest packing of clusters of nucleons⁵, I have found that the magic numbers have a very simple structural significance: 2 and 8 correspond to the closed shells $1s^2$ and $1s^21p^6$, and the others to a closed-shell core with an outer layer (the mantle of the nucleus) containing the number of spherons (helions⁶, He⁴, tritons, H³, or dineutrons) required to surround the core in closest packing.

Triangular (icosahedral) closest packing, as found, for example, in the intermetallic compound⁷ $Mg_{32}(Al,Zn)_{49}$, involves the sequence 1, 12, 32, 72 of spheres in successive layers. These numbers are approximated by the equation $n_0 = (n_i^{1/3} + 1.30)^3 - n_i$, in which n_0 is the number of spheres in an outer layer and n_i is the number in the core. (The form of this equation corresponds to assigning equal effective volumes to the spheres, and the value of the constant reflects the nubbly of the surface and the packing of outer spheres into pockets of the core.) This equation can be applied to obtain the number of spherons in the successive layers in a nucleus, and thus to obtain the sequence of nucleonic energy-levels. Sub-shells (with given value of l) occurring once (as $1s$, $1p$, etc.) are assigned to the mantle of spherons, those occurring twice ($1s$ and $2s$, for example) to the mantle and next inner layer, and so on. Thus I interpret the configuration for N or $Z = 50$, given above, as representing 8 neutrons or protons in the

core ($1s^21p^6$) and 42 in the outer layer ($2s^22p^61d^{10}1f^{14}(1g9/2)^{10}$).

The application of the packing equation leads to sequence of levels essentially as given by Mayer and Jensen, but often with sub-sub-shells for different layers being filled over overlapping ranges of values of N or Z . For example, the $3s1/2$, $2d3/2$, and $1h11/2$ sub-sub-shells all begin to be occupied at about N or $Z = 60$ and are completed at about N or $Z = 82$.

Fig. 1. The magic-number structures of atomic nuclei

The configurations found in this way for the magic numbers are given in Table 1 and Fig. 1. Each of the first two represents a completed shell. The third (20) has a completed shell as core and another as mantle. Each of the others has a core of a completed shell or two completed shells, with a mantle that is required by the packing to include a sub-sub-shell $(1g9/2)^{10}$ for 50, $(1h11/2)^{12}$ for 82, and $(1i13/2)^{14}$ for 126. Until 184 reached, there are no other values of N or Z for which the packing equation leads to a core consisting of layers that are completed shells.

Table 1. NUCLEON CONFIGURATIONS FOR MAGIC NUMBERS

N or Z	Mantle	Core or outer core	Inner core
2	$1s^2$		
8	$1s^21p^6$		
20	$2s^21p^4d^{10}$	$1s^2$	
50	$2s^22p^4d^{10}1f^{14}(1g9/2)^{10}$	$1s^21p^6$	
82	$3s^22p^4d^{10}1f^{14}1g^{12}(1h11/2)^{12}$	$2s^21p^4d^{10}$	$1s^2$
126	$3s^23p^4d^{10}2f^{14}1g^{12}1h^{14}(1i13/2)^{14}$	$2s^22p^4d^{10}1f^{14}$	$1s^21p^6$

I conclude that the stability that characterizes the magic numbers results from the completion of shells of a single layer (2, 8) or two layers (20) of spherons, or, for the larger magic numbers (50, 82, 126), for the core layer the mantle having a completed shell plus a completed sub-sub-shell.

Size Analysis in the Sub-sieve Range by Electronic Counter

THE electronic apparatus for the rapid measurement of particle content and size distribution, known as the Coulter counter¹, is finding increasing application in many fields. A known volume of an extremely dilute suspension of particles in a conducting fluid flows through a standard interchangeable aperture having an immersed electrode either side. The particles traverse the aperture substantially one at a time, causing an attendant change in electrical resistivity proportional to the volume of the particle passing through the aperture. The amplified signals pass through a gate circuit which ensures that only pulses greater than a pre-selected threshold value are counted; thus, the pulse count records the number of particles greater than a certain size. A typical count requires about 5–25 sec and is performed at a rate up to 10 particles/sec. A size range of about 500–0.5 μ can be covered, therefore overlapping with sieving, microscope and sedimentation methods.

After applying certain corrections (for example, for the effect of coincident particle passage) and calibration constants, the basic data relate the numbers of particles greater than a stated size to the particle volume. This information is readily converted into the relationship between cumulative volume above a stated size (V) and particle size (X).

Size analysis results are usually quoted as cumulative volume (or weight) percentage above (or below) a stated size versus size. For this the total volume, V_∞ , or weight of particles in the measured sample must be known. However, the instrument response to sub-micron particles obscured, if not by insensitivity then by factors such as background noise and insufficient counter frequency response. Thus, the finest material in a distribution may be below the range of measurement, so that the cumulative data cannot be expressed as a fraction or percentage.

It would be possible to obtain the total solid volume gravimetrically, but one of the potential advantages of the Coulter counter is that, in the suspension prepared for analysis, the concentration of solids need not be known; additionally, the gravimetric analysis would need to be highly sensitive. The maker's instruction manual suggests a trial and error method in which the total volume of particles traversing the aperture is estimated by choosing the value providing the best straight line when cumulative percentage is plotted against size on a probability X logarithmic grid. A similar curve-fitting procedure was suggested by Batch². Simple extrapolation of the plot of cumulative volume against size either on simple arithmetic or logarithmic X arithmetic co-ordinates affords another approximate method of estimation. Experience indicates that both methods are unreliable.

The problem is determination of an unknown asymptote³, and a somewhat analogous situation exists with the sedimentation balance where an inordinately long time is necessary for the finest material to sediment, or because it remains permanently in suspension on account of Brownian movement⁴. A direct method for graphically estimating the missing finest material⁵, or what amounts to the same thing, the value of V_∞ , is presented here. While sub-micron material is the main concern here, the method may be applied to any size below the range of the aperture in use.

The equations of size distribution⁶ assumed are the Gates-Gaudin-Schuhmann type:

$$V = V_\infty \left[1 - \left(\frac{X}{X_0} \right)^N \right] \quad (1)$$

and the Rosin-Rammler type:

$$V = V_\infty [1 - \exp(-X/X_0)^n] \quad (2)$$

where X_0 is a parameter of mean size, and n and N parameters of distribution spread. These are closely

similar for the finest 20 per cent of the material and their correspondence at 30 per cent is within 1 per cent absolute. Consequently one or other equation could be used when the missing material is of the order of 20 per cent of the total volume counted. Correspondence with the logistic and probability distributions is less good, being about 0.5 per cent in absolute error over the finest 10–15 per cent of the material.

Equation (1) can be represented by the pair of equations⁴:

$$X_{r-1} = qX_r \quad (3)$$

and:

$$\left(\frac{V_{r-1}}{V_\infty} - 1 \right) = q^N \left(\frac{V_r}{V_\infty} - 1 \right) \quad (4)$$

while equation (2) can be represented by the pair of equations⁴:

$$\frac{V_{r-1}}{V_\infty} = \left(\frac{V_r}{V_\infty} \right)^q \quad (5)$$

together with equation (3), where r is an integer increasing as X decreases and as V increases and $q > 1$ and is constant. A solution of equations (4) and (5) is $V_{r-1} = V_r = V_\infty$; by plotting V_{r-1} against V_r on a squared grid for equation (4) and on a log-log grid for equation (5), V_∞ is obtained from the point of intersection of the resultant line with the line, $V_{r-1} = V_r$.

Table 1. SIZE ANALYSIS OF -300 B.S.-MESH QUARTZ BY COULTER COUNTER

Particle size (X, microns)	Cumulative vol. (V, arbitrary units)	Particle size (X, microns)	Cumulative vol. (V, arbitrary units)
60.40	0	33.12	5,100
38.68	3,528	23.44	9,100
24.19	8,792	16.56	12,700
15.28	13,523	11.72	15,600
10.68	16,365	8.28	17,600
9.33	17,183	5.86	18,669
7.40	18,103		
5.86	18,669		

The procedure for applying this method is to plot the original data V against X and interpolate values of V_{r-1} , V_r , V_{r+1} , etc., corresponding to values of X_{r-1} , X_r , X_{r+1} , etc., diminishing in geometric progression in accordance with equation (3) (see Table 1). The last actual reading of V and X should be included in this sequence. Interpolation at this stage has the advantage of smoothing experimental errors. Having determined V_∞ from a plot of V_{r-1} against V_r (Fig. 1) the size distribution Y against X ($Y = V/V_\infty$) is obtained in the usual manner.

For this particular example, V_∞ has been estimated to lie in the range 20,500–20,600 by independent observers. The ordinary extrapolation method, on the other hand, yielded estimates ranging from 19,500 to 21,200. The estimation of V_∞ from the plot of V_{r-1} versus V_r can be

Fig. 1. Graphical determination of V_∞ . Data from Table 1. $q = \sqrt{2}$; last value of $X = 5.86 \mu$; $V = 18,669$

made as accurate as one desires. Larger graphs can be drawn and more points taken, either by diminishing the ratio, q , or by taking overlapping sets of points; for example, for a ratio of $\sqrt{2}$, take the sets 5.86, 8.28, . . . and 6.0, 8.5, . . . and 6.5, 9.2, . . . etc.

If $n = 1$ the values of X may be selected in arithmetic progression; this case has been considered previously⁴. Should the plotted points not lie on a straight line the curve would probably fit another function having an unknown asymptote. However, the last point should be sufficiently close to the line $V_{n-1} = V_r$ for an extrapolated curve to give a reliable estimate of V_∞ .

This graphical procedure has been used in a number of similar applications all involving unknown asymptotes^{4,5,7,9}. Finally, a warning must be issued: this is an extrapolation technique; there is no certainty that the size distribution law outside the measured range is the same as that inside. Thus, results obtained from this method must be used with discretion; it is not a substitute for an effective and rapid particle size analysis technique for the sub-micron region, the search for which must continue.

Ionization Times in Shock-heated Potassium Vapour

THE sudden heating of a gas in a shock wave has often been used to study relaxation effects¹⁻³. Most experiments on relaxation times for ionization have been carried out with inert gases, which have first ionization potentials in the range 12-24 V. These measurements have suggested^{1,4,5} that the atoms are ionized via excited states; but the results may have been influenced by the unknown effect of impurities.

The monatomic character of inert gases, and the consequent absence of complications due to dissociation, make the inert gases attractive at first sight; but in fact the high ionization potential allows only a small amount of ionization in a pressure-driven shock-tube and almost any impurity may dominate the ionization process. Moreover, the high temperature required to achieve a reasonable degree of ionization results in a short cooling time, which may be less than the ionization time if the density is low; and complications arise because of secondary ionization and ion excitation, since the relevant critical potentials are of the same order.

It has often been pointed out⁶ that these difficulties could be avoided by using alkali metals (these have ionization potentials of 4 or 5 V, whereas the first excitation potential of their ions is several times this figure). But the great technical problems of passing shocks through such vapours have to be overcome. Such a shock tube is now in operation and ionization relaxation times have been determined by measuring the current in probes flush with the sides of the tube.

The shock tube, which was specially developed for alkali metal vapours, is of stainless steel and has ground-in stainless steel valves and a copper diaphragm. It is immersed in an oil vapour furnace at 300°-400° C.

Liquid potassium metal is fed into a boiler. The latter can be isolated from the tube, cooled during evacuation and then opened and allowed to heat up to admit vapour after the shock-tube has been isolated from pumps. The boiler is kept at a temperature some 10° lower than that of the furnace. Initial potassium pressures of 0.3-3 torr can be obtained by varying temperatures of the boiler and furnace. Helium-argon mixtures at a pressure of about 15 atmospheres are used in the compression chamber to produce shocks with Mach numbers of between 3 and 8 in the potassium vapour.

Metal probes of 'Nilo K' (an alloy of iron, cobalt and nickel), about 1 mm diameter and insulated from the shock-tube by a ceramic seal, are fitted flush to the wall of the expansion chamber and connected through a series resistor to the positive terminal of a 4.5-V battery, the other terminal being connected to the metal shock-tube. The series resistor is adjusted by experiment to have about the same value as the resistance of the probe in the equilibrium plasma behind the shock wave. Oscillograms of the probe voltage indicate the electron current to the probe. Probes mounted at two stations 13 cm apart show traces on a double beam oscilloscope from which the shock speed can be measured. The first probe also operates a trigger-amplifier which triggers the oscilloscope immediately and also triggers a fast time-base oscilloscope after a variable delay. This delay is arranged by experiment so that the fast oscilloscope is triggered just before the shock reaches the second station. The fast oscilloscope records on the upper beam the probe voltage at the second station and on the lower beam the voltage on another probe mounted opposite this with a small reflecting obstacle immediately behind it. Fig. 1 shows a typical trace. The lower trace shows a fast rate of ionization, but no change in the onset time. This indicates that there is no dormant period between the shock and the initial fall of the probe voltage.

Relaxation times τ (defined as indicated in Fig. 1) have been measured for shock Mach numbers M in the range 3.2-4.6 and initial particle densities n from 6×10^{16} to 2×10^{18} per c.c. Higher densities and shock Mach numbers resulted in relaxation times less than 1 μ s which could not be resolved by the probe. Lower densities and Mach numbers failed to trigger the amplifier, probably because of a reduction in running time.

Fig. 2 shows a graph of $\log n\tau$ against $1/T$ (where T is the temperature of the shocked gas calculated from M). If the ionization relaxation time obeys an Arrhenius law of the type:

$$\tau \propto (1/n) \exp(eV/kT) \quad (1)$$

where V is some critical potential, the slope of the graph should give V . A least squares fit gives $V = 1.9 \pm 0.3$ V. The first potassium excitation potential is 1.6 V. Since the ionization potential of potassium is 4.3 V, these results indicate a multi-stage ionization process dominated by the rate of excitation of the atom. The measured values of τ are for values of n and T much lower than those used by previous investigators. If the measurements for

Fig. 1. Typical probe voltage traces. Upper trace, plain probe; lower trace, reflector probe

Fig. 2. Ionization times in shock-heated potassium vapour

on^{1,7} are extrapolated according to expression (1) to values of n and T , values of τ some 10^9 times greater than for potassium are obtained. This is reasonable considering the much lower potentials and higher cross-sections of the alkali metals. Though experiments have previously been performed on argon seeded with small amounts of alkali metal⁸ these experiments are, so far as we know, the first of this type to be made in a pure metallic vapour.

We thank the United Kingdom Atomic Energy Authority financing the contract under which this research was formed.

METALLURGY

Interconnexion of Silicon in Modified Aluminium-Silicon Eutectic

WHEN the aluminium-silicon eutectic is rapidly frozen, when sodium is added in small quantities (< 0.017 per cent), the structure apparently is modified from an acicular form to a globular form of the silicon phase¹⁻⁷. The reason for the modification is still a matter of controversy⁸, and a review of present-day theories is given by Chadwick¹.

All the theories presented so far claim that the fine dispersion of silicon particles is produced by an increased nucleation frequency of silicon particles at a temperature lower than the equilibrium eutectic temperature. The lowering of the temperature is attributed to either a reduction in the initial nucleation frequency^{1,3,6,9-12} or restricted growth^{2,4,7,13-15}.

All present theories assume that each of the silicon particles in the modified structure is separate from, and not connected to, a neighbouring particle. The work reported here shows that this assumption is not valid.

A rapidly cooled sample of high-purity aluminium-silicon eutectic was polished metallographically to reveal

the modified structure. The sample was then etched for 24 h in a 10 per cent hydrochloric acid solution, and for 1 h in a solution of 2.5 c.c. hydrochloric acid, 2.0 c.c. nitric acid, 0.75 c.c. 40 per cent hydrofluoric acid, and 40 c.c. water to dissolve the aluminium phase and leave the silicon untouched.

The silicon phase in this modified structure was found to be interconnected in any one grain, even when the grains were 2 mm in diameter. The same result was obtained when the structure of the sodium-modified alloy was examined.

From these observations, it is apparent that in the aluminium-silicon eutectic the silicon phase grows from a common nucleus in each eutectic grain in both the rapidly cooled and sodium-modified structures. In fact, the structure has not been 'modified' in the normal usage of this word. There is no change in the basic growth mechanism, and the structure is not globular. The silicon takes up a very fine interconnected acicular structure.

GEOLOGY

Re-classification of the Ethiopian Cainozoic Volcanic Succession

RECENT exploration and field-work in Ethiopia, in particular gravity-geology surveys made by Prof. P. Gouin, Dr. A. S. Rogers and me, have shown the Cainozoic volcanic succession in association with the Ethiopian Rift System to be more complicated than previously suspected.

The classic work of Blanford¹ established the existence of an older, extensive, pre-rift series of lavas, the Trap Series, covered by a younger, post-rift series of lavas, the Aden Series, the latter largely confined to the rift-system itself. Furthermore, Blanford divided the Trap Series into an earlier group of basalts, the Ashanghi Group, unconformably overlain by basaltic and silicic lavas and tuffs, the Magdala Group. This classification was generally accepted until the work of Merla and Minucci², who denied the existence of Blanford's unconformity, considering the tilting of the Ashanghi Group basalts to be due to post-Trappean tectonic movements. Merla and Minucci's revision of the nature of the Trap Series succession has been largely accepted by later workers, including Dainelli³ and myself⁴, though Blanford's terminology has been retained on the basis of lithology.

However, the recent discoveries of unconformities within the Trap Series in various parts of Ethiopia, by Jepsen and Athearn⁵, Rogers⁶ and me⁷, have led Rogers and me to a reconsideration of Merla and Minucci's arguments and a re-examination of the critical Ashanghi-Magdala region. The results of this new work (details to be published elsewhere⁸) have included the re-establishment of Blanford's unconformity, and the implications of this finding together with additional data from recent studies in the Ethiopian Rift System are summarized here.

The Trap Series, as defined by Dainelli², can now be divided into three major units: (3) great shield volcanoes of the Plateaux, composed of basalts, alkaline silicies and undersaturated lavas. Generally conformable on: (2) fissure and central-type basalts, with silicic lavas and pyroclasts becoming more abundant near the top. Unconformable on: (1) fissure basalts, with localized thick silicic lavas in Afar. Unit 1 is the Ashanghi Group of Blanford, and units 2 and 3 the Magdala Group. It would, however, be preferable to exclude unit 3 from the Magdala Group for reasons of age-range, localization and petrology. The term 'Shield Group' might be acceptable, and will be used here.

The re-establishment of Blanford's unconformity has led to the important finding that the Ashanghi Group lavas were down-warped (and flowed down?) into Afar and the Main Ethiopian Rift during and immediately subsequent to their extrusion^{4,8}. The sites of the fissure-feeders for these lavas coincided with the Plateau-Afar structural margin^{4,7}, where down-warping was particularly severe and complicated by strong north-south compressional movements. There is evidence at Amba Alaji (12°58' N., 39°32' E.) that these compressional movements had begun during the deposition of the now isoclinally folded Jurassic marine sediments^{8,10}. Furthermore, the Ashanghi lavas seem to have been largely confined to the region and margins of the down-warped proto-rift system; they have been dated as Eocene by Lipparini¹¹ and Grasty *et al.*¹².

The ensuing initiation of the Arabo-Ethiopian Swell in the Upper Eocene resulted in a moderate uplift of the whole region^{8,13} (cf. Dainelli², who considered the larger part of the uplift of this Swell to have occurred at this time). This uplift was followed, over most of Ethiopia, by a duration of volcanic quiescence sufficient for appreciable peneplanation to occur across the warped Ashanghi lavas along the Plateau-Afar margin, prior to the first Magdala Group eruptions. On the northern Somalian Plateau, however, there was either little or no break between the Ashanghi and Magdala eruptions, or else a very small degree of uplift in the Upper Eocene.

Unlike the Ashanghi lavas the Magdala lavas are thickly developed over much of the Plateaux away from the Rift System, perhaps because of their dominant extrusion from aligned centres on a gently sloping surface. These centres lay just outside the outer structural margin of Afar^{4,7} on a surface suffering contemporaneous slight upwarping towards the Rift System. Important fissure eruptions of basaltic and silicic lavas occurred along the inner structural margins of Afar, lavas which were included by Gortani and Bianchi¹⁴ as the earliest lavas of the Aden Series. The Magdala Group lavas have been dated as Oligocene and early Miocene^{3,12}.

In the Burdigalian-Helvetian period there occurred the major uplift of the Arabo-Ethiopian Swell together with rift faulting on a large scale^{13,15}. The great shield volcanoes, of which the culminating example is that of Semien¹⁶, were initiated at, or shortly after, this tectonic paroxysm. Despite the tectonic intervention, however, the lack of significant unconformity between the Magdala Group and the Shield Group indicates a continuing though modified single volcanic episode. The Shield Group volcanoes all lie outside and in many cases well away from the Rift System. Until more radiometric ages are available it remains uncertain what form, if any, volcanicity took within the Rift System during Shield Group times, but it seems likely that the upper part of the Magdala lavas of the Rift System are temporally (but not petrologically) equivalent to the Shield Group of the Plateaux. The Shield Group is dated as late Miocene-early Pliocene, but isolated volcanoes continued their activity throughout the Pliocene and even into the Pleistocene. A good example of such late activity is provided by the alkaline rhyolitic centre of Mt. Kakka on the Somalian Plateau.

As previously indicated by me⁴, there was no obvious interval between the last Trap Series eruptions and first Aden Series eruptions; indeed, recent work suggests an overlap and a corresponding difficulty drawing a precise line between the two, especially with the Rift System. The earliest lavas ascribed to the Aden Series are the Pliocene hyperalkaline, coarsely crystal lavas of which the famous Adua-Axum suite on northern Ethiopian Plateau is typical. These lavas aligned along approximately east-west lines.

Pleistocene volcanicity occurred throughout at least two phases of renewed uplift of the Arabo-Ethiopian Swell¹³, being characterized by violent silicic eruptions in the Rift System but by basalts on the Ethiopian and Somalian Plateaux. Such basalts dammed back Lake Tana in the down-warped and tilted Tana basin. In the Pleistocene and Holocene times transcurrent faulting along the Main Ethiopian Rift^{7,17} was accompanied by carbonatitic activity, while the latest lavas erupted from the fissures and volcanoes of the Rift System have been either scoriaceous olivine basalts or pantelleritic and comenditic obsidians.

No detailed table of the succession of lavas and tectonic events during the Cainozoic in Ethiopia is presented here as information on the Trap Series succession on the southern part of the Ethiopian Plateau is still being gathered. More important, as hinted in this communication, local variations and complexities both in lava thickness and types and in contemporaneous tectonic movements are proving to be more intricate than can be satisfactorily expressed in any correlation table at present. In this regard the recent work of Merla¹³ on erosive surfaces in south Ethiopia and north Kenya, and particularly his consideration that the Plateau surface is the result of post-Trappean peneplanation during the Oligocene, must be treated cautiously before being extended into central Ethiopia⁸. Indeed, the conclusions of different investigations of the behaviour of erosion surfaces in southern Ethiopia are so contradictory^{13,18,19} as to emphasize the need for a dispassionate resumé to indicate the critical regions needed for further examination.

Finally, while this article has been briefly concerned with the major Cainozoic volcanic episode in Ethiopia it must be noted that there was important volcanicity during Mesozoic times along the present Red Sea coast region. Both north of Massawa and east of the Danakil Alps andesitic lavas occur which are unconformably overlain by the thick Eocene-Miocene Dogali geosynclinal sediments of the proto-Red Sea trough; in the Danakil Alps these same lavas rest unconformably on late Jurassic limestones, thus suggesting an end-Jurassic or early Cretaceous phase of vulcanism.

Palaeomagnetism of the Isachsen Diabasic Rocks

In a previous article by two of us¹ it was suggested that a belt of diabasic rocks south of Isachsen in the Canadian Arctic Archipelago appeared to be of Cretaceous on the basis of its palaeomagnetism. On the other hand, whole rock potassium/argon age determinations on two of the samples studied (1-A and 10-B) indicated a Cretaceous age (241 and 249 m.y.), in conflict with the palaeomagnetic data. No reasonable explanation for this incompatibility could be advanced at the time and, since then, one of us (R. K. W.) has re-determined the age of two of the samples (10-B), using a mass spectrometer with higher sensitivity than was used in the original determinations. Another sample (9-B) was sent to the Geophysical Branch laboratories, U.S. Geological Survey, and a third one (9-A) was split and one half of it was sent to N. J. Snelling at the University of Oxford, while the other half was dated in the laboratories of the Geological Survey of Canada with the new high-sensitivity instrument. The ages obtained in these four whole rock determinations are listed in Table 1.

Table 1

Sample	Laboratory	% K	% ⁴⁰ Ar (radio-genic)	⁴⁰ Ar/ ⁴⁰ K	Age* (m.y.)
10-B	Geological Survey of Canada	0.93	39	0.00656	109
1-A	"	0.96	40	0.00660	110
1-A	Oxford (ref. 2)	0.94	39	0.00618	103
10-B	U.S. Geological Survey (ref. 3)	0.75	66	0.00612	102

Constants: $\lambda_{\beta} = 4.72 \times 10^{-10} \text{ y}^{-1}$; $\lambda_{\epsilon} = 0.585 \times 10^{-10} \text{ y}^{-1}$; $^{40}\text{K} = 0.0119 \text{ per cent.}$

It is apparent from the consistency of these determinations that the rocks dealt with in the original paper¹ are of Lower Cretaceous age and that the pole position derived from their mean palaeomagnetic direction should be considered as a fairly reliable one for Lower Cretaceous with respect to the North American Continent.

We thank Dr. N. J. Snelling of the University of Oxford and Dr. S. S. Goldich, formerly of the U.S. Geological Survey, for their assistance.

750° C, for 1 h, and treated with ethylene glycol, glycerol and ammonium nitrate. The chemical compositions and differential thermal analysis curves of both natural and piperidine-treated specimens are shown in Table 2 and Fig. 3.

All these data correspond to those of the so-called random interstratified minerals of illite and montmorillonite reported by many investigators, but the X-ray reflexion at about 29 Å in the natural specimen (uppermost in Fig. 2) cannot be expected from the random structure. Sato has proposed² that the interstratified mineral would take its layer arrangements to minimize the total interaction energy, and that it should be treated for at least Rechweite

Fig. 3. Differential thermal analysis curves of the interstratified mineral. A, Natural; B, treated with piperidine

Fig. 4. Illite and montmorillonite models used in calculation of X-ray intensity

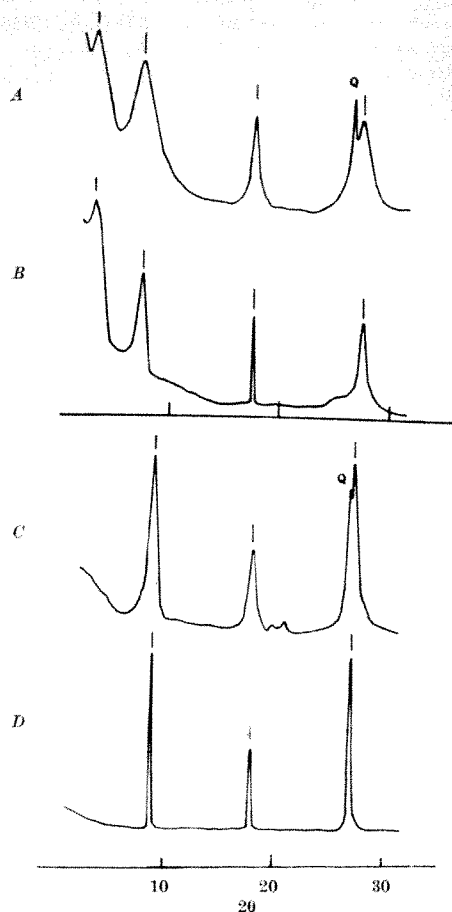

Fig. 5. X-ray reflexion curves along (00ζ). A and B, air dried, observation, calculation, *N* = 60 (total number of layers); C and D, heated at 450° C, observation, calculation, *N* = 150

g = 1, not *g* = 0 (random). With this in mind, X-ray reflexion curves along (00ζ) in the air-dried specimen and the specimen heated at 450° C—the intensity of which was calibrated at low angles in consideration of the slit system used—were carefully compared with mathematical curves. The calculation was based on the models shown in Fig. 4. As a consequence, it was found that the specimens were interstratified mineral of illite and montmorillonite, which the component of illite (*W_I*) is 0.72, that of montmorillonite (*W_M*) is 0.28, the probability of finding illite succeeding illite (*P_{II}*) is 0.611, and the probability of finding montmorillonite succeeding montmorillonite (*P_{MM}*) is 0.0. The result is shown in Fig. 5 and Table 3 (and graph in ref. 2).

We thank Prof. T. Sudo for his advice.

CRYSTALLOGRAPHY

Pairs of Spiral Etch Pits in Ice Crystals

In an earlier communication¹, I reported observations of spiral etch pits in ice crystals which had quite large step heights (200–2000 Å). At that time no detailed explanation of their origin was offered; but in the course of further investigations² of ice crystal etch pit, these etch pits were postulated to correspond to dislocations. I

ny crystals, however, the step height of the spiral etch is quite large in comparison with the Burgers vector, and it is thus impossible to determine the causal factor³. Recently, an attempt was made to verify the mechanism involved in etching in ice crystals, and it is found that pairs of etch pits may develop on the {001} surface in which the pairs consist of one right-handed and one left-handed spiral. These are often remarkably similar to those one would expect from a Frank-Read source (Figs. 1 and 2). Sometimes, pairs of pits with a unidirectional spiral are observed (Fig. 3). It is of interest to note that each pair of etch pits is closely aligned to crystallographic orientations such as $\langle 10\bar{1}0 \rangle$ or $\langle 11\bar{2}0 \rangle$. In Figs. 1 and 3, the distance between a pair of pits is about 8μ and in Fig. 2 the distance is 50μ . If we assume that these spiral etch pits correspond to screw dislocations lying on a prism plane, the Burgers vector should be $\langle 0001 \rangle$, which vector, although possible, has never been reported in ice crystals or in any other hexagonal crystals. If this assumption is correct, the existence of paired etch pits consisting of one left-handed and one right-handed spiral implies a dislocation half loop on a prism plane (Figs. 1 and 2). With regard to the large angle of the pitch of the spiral, one interpretation, based on the presence of a dislocation or a helical dislocation, has been given by Ellis⁴ and Amelinckx *et al.*⁵, and another by Lang⁶ which is not based on the presence of dislocations. It is possible that the large step heights observed are not formed from screw dislocations with Burgers vectors of this magnitude, but develop during the etching process from aggregations of asymmetrical spirals which develop about the point on the surface at which

Fig. 1. A pair of etch pits on a {0001} plane. Note that one is right-handed and the other is left-handed

Fig. 2. A pair of fairly widely separated etch pits on a {0001} plane. One spiral is right- and the other left-handed

Fig. 3. A pair of etch pits with unidirectional spirals

the dislocation emerges. This closely resembles the mechanism proposed by Amelinckx *et al.*⁵ which requires a helical dislocation; but there is no reason why a screw dislocation could not develop such a spiral. Although this appears to be a plausible explanation of the large angle of pitch observed, further detailed investigation is required for any definite conclusions.

Recently, the first direct observation of dislocation in ice crystals has been reported by Hayes and Webb⁷, using Lang's X-ray transmission method. They found that dislocation segments in the (0001) plane are quite long and are oriented parallel to $\langle 10\bar{1}0 \rangle$ and $\langle 11\bar{2}0 \rangle$. Judging from the results of direct observations and from successive etching of basal surface, which give a three-dimensional picture of the dislocation arrays, the non-basal segments of these dislocations are probably very short, and one may expect that there would be a long distance between a pair of pits.

If this speculation is correct, dislocations with $\langle 0001 \rangle$ Burgers vectors may exist in ice crystals and may provide a clue to an understanding of some unexplained observations of dislocation movement in ice crystals.

CHEMISTRY

Simultaneous Oxidation and Reduction of Diphenyl Picrylhydrazyl on Surfaces: Evidence for Catalytic Activity of F-centres

We have recently found that diphenyl picrylhydrazyl undergoes intermolecular oxidation and reduction quite rapidly on carbon black (Cabot: 'Carbolac 2') and on a high area TiO_2 (anatase) which has almost a monolayer of sulphuric acid on its surface.

With 2 g of diphenyl picrylhydrazyl dissolved in 250 c.c. of benzene and 25 g of anatase (263 sq. m/g. containing 7.55 wt. per cent of sulphuric acid) the reaction is more than 90 per cent complete in 90 min.

The non-volatile products obtained after filtering and distilling off the benzene are dissolved in chloroform. The benzene distillate contains considerable quantities of quinone. The non-volatile products can be seen to contain yellow needles of crystalline quinone which can be

picked out (m.p. 114°–115°, mixed m.p. with quinone 114°–115°). Separation was performed by thin-layer chromatography.

The main product is diphenyl picerylhydrazine, m.p. 169°–170°, mixed m.p. with diphenyl picerylhydrazine 169°–170°, and in most runs the amount of it corresponds to a reduction of 75 per cent of the radical. This compound results from self-reduction of the hydrazyl radical while the quinone results from simultaneous oxidation of another molecule of the radical in consecutive steps. 2',4',6'-trinitro-4-aminodiphenylamine (piceryl phenylenediamine) is isolated from one of the bands almost pure; usually about 0.10 g, m.p. 142°–143° (found: C, 45.65, 45.83; H, 2.90, 2.67; N, 21.50, 21.24; mol. wt. (Rast 290); calculated for $C_{12}H_9N_3O_6$: C, 45.15; H, 2.84; N, 21.94; mol. wt., 319).

The only obvious way to make this compound is by the action of piceryl chloride on phenylenediamine, but this has been shown to yield a high melting product.

According to Wedekind¹, the product is an addition product (found: C, 40.90; H, 3.14; N, 19.91). He states that this corresponds to the addition product $C_{12}H_{10}N_3O_6Cl$ (calc. C, 40.48; H, 2.81; N, 19.73). Wedekind's work was repeated by Morgan and Micklethwait². The product has a melting point of 185°–187° and forms a sparingly soluble salt with strong hydrochloric acid, but they give no analysis.

A consideration of the possible resonance forms involving the para groups would lead one to expect that the salt would be unstable. Attempts to hydrolyse the compound, m.p. 142°–143° (which analyses for *N*-piceryl phenylenediamine), to its components yielded a mixture of alkali and acid insoluble products.

The following series of reactions is one explanation of what has obviously happened.

Reduction :

Oxidation :

Rearrangement :

Oxidation :

The two oxidation steps require two further moles hydrazyl yielding a product which is the *N*-piceryl substituted indanilin. Hydrolysis yields quinone and piceryl phenylenediamine as found. It could also yield picramid and *p*-aminophenol. If the first oxidation step involves the ortho position the indanilin then has an ortho-quinoid linkage and would yield orthoquinone, a difficult substance to isolate. If the rearrangement (equivalent) of the *p*-hydroxydiphenyl piceryl hydrazine involves the ortho position of the phenyl group, processes involving a cyclic intermediate are possible. Likewise the *p*-hydroxy diphenyl piceryl hydrazine could be oxidized to the substituted hydrazyl. The total amount of *N*-piceryl diphenylamine, if all the reaction went as outlined should be 0.4 g.

The reaction occurs very slowly on sulphuric-acid-free TiO_2 (anatase) and silica gel. It occurs rapidly in sulphuric acid saturated benzene. On 'Carbolac 2' without any addition of acid or water the reaction occurs at one-fifth the rate of that on the anatase (7.5 per cent sulphuric acid), yielding the same products.

During the reaction on the anatase no sulphuric acid was removed. Results to be reported elsewhere show that on all surfaces the reaction is first order in the radical. This indicates a mechanism involving mobile *F*-centres or the equivalent as the only possibility.

The triggering reaction must be the addition of an electron to the hydrazyl in the reduction part, since the oxidation part involves consecutive reactions. On the anatase the reaction yielding the electron is:

where *X* represents any group covalently linked to titanium. The reaction taking the electron in the oxidation part is:

These two reactions yield a stoichiometric balance with the reduction and oxidation equations written here. The first involves the destruction of an *F*-centre which must appear elsewhere if the surface is mobile. The electron to produce an *F*-centre comes from the oxidation step.

Correlation of Sodium Atom Reaction Rates with Electron Capture Cross-sections

THE classic Polanyi flame work^{1,2} explored the reactions of sodium atoms with a very wide range of halogen compounds. For some of these the rate constants were found to be extremely large ($\sim 10^{14}$ c.c. mole⁻¹ sec⁻¹), corresponding to "reaction on more than every gas-kinetic collision". This was attributed to an electron-jump mechanism,

Here essentially all collision trajectories that pass within the radius r_c at which formation of the ion-pair becomes possible lead to reaction³. This radius is given by $e^2/r_c = I(Na) - E^v(X-R)$, where *I* denotes the ionization potential of the alkali atom and E^v the vertical electron affinity of the halogen molecule. Recently, several alkali atom reactions of this type (with $X-R = Br_2, ICl, PBr_3, CBr_4, SnCl_4, SF_6$, etc.) have been examined in molecular beam scattering experiments⁴. The form of the angular distribu-

ns of elastic and reactive scattering and other detailed nautical properties observed in these experiments can very plausibly interpreted in terms of the electron-jump mechanism.

However, a much larger class of 'reactions with inertia' is also examined in the Polanyi sodium flame experiments. These cover a broad spectrum of reactivity and many proceed at rates which are $\sim 10^4$ times slower than action at every collision^{1,2}. The simple electron-jump mechanism cannot apply to these reactions, as the cross-sections correspond to such small values of r_c that other chemical interactions must become very important.

is therefore of particular interest to note a simple relation which indicates that even for this class of actions the electron affinity of the reactant molecule plays a dominant part.

Recently, Lovelock has estimated electron absorption coefficients for many compounds from gas chromatography³. Under the conditions of measurement this coefficient is a thermodynamic parameter. It governs the thermal equilibrium between electrons, ions, and neutral molecules and is essentially a measure of the adiabatic electron affinity⁴. (The difference between the vertical and adiabatic electron affinity becomes irrelevant for reactions with small values of r_c as the bond distances in the transition state are expected to be considerably displaced from the equilibrium values in the isolated reactant molecule.) The electron absorption coefficients show systematic variations with chemical structure which Lovelock has mapped out. His results are remarkably similar to those found for Na atom reaction rates in the Polanyi experiments. For example, the following factors markedly enhance both capture of thermal electrons and reaction with Na atoms: (1) change of the halogen atom, in the order $F \rightarrow Cl \rightarrow Br \rightarrow I$; (2) presence of an oxygen atom in addition to the halogen; (3) multiple substitution which increases the number of electrophoric groups or brings them closer together; (4) location of the halogen atom at an allylic or benzylic position (double bond in β -position to X atom). Also, the rates for both processes are depressed when (5) the halogen atom is adjacent to an ethylenic double bond or a benzene ring (double bond in α -position to X atom).

Only order-of-magnitude values are known for both the electron absorption coefficients and the Na reaction rate constants. However, the correlation holds for a wide variety of compounds and in the case of factors (1) and 3) covers a range of $\sim 10^6$ in reactivity. Fig. 1 gives a

Fig. 1. Correlation between electron absorption coefficients (at 100° C) and rate constants for reaction with sodium atoms (at 250° C). The line is included merely to indicate a slope of unity. The values of the electron absorption coefficients are relative to that for chlorobenzene, which is taken as unity.

comparison for a few chlorinated hydrocarbons and illustrates the operation of factors (3)–(5). The values given for the electron absorption coefficients⁵ are relative to that for chlorobenzene. Approximate absolute values can be assigned since the cross-section for chlorobenzene has been estimated⁷ to be ~ 0.1 to 1 Å^2 . Thus an absorption coefficient of 10^3 corresponds to a cross-section of about $100\text{--}1000 \text{ Å}^2$. For the Na reactions the cross-sections can be roughly estimated from the ratio of the rate constant to the average thermal velocity; a rate constant of 10^{14} corresponds to a cross-section of about 30 Å^2 .

The extended parallelism between electron affinity and reactivity indicated by this correlation is perhaps to be expected from familiar arguments concerning stabilization of the transition state by charge delocalization^{8,9}. For these simple gas phase reactions, it seems likely that the factors (1)–(5) are mainly governed by delocalization. Although these factors sometimes operate in a qualitatively similar way for reactions in solution, they are often overcome by other effects⁹.

A Preparation of Cementite

SEVERAL methods for the preparation of the carbides of iron have been reported in the literature. In order to obtain a satisfactory product it may be necessary to use a relatively high temperature¹, or long periods of reaction during which reaction conditions must be controlled within narrow limits for several weeks^{2,3}. Using these methods we found considerable difficulty in preparing a sample of iron carbide which was sufficiently pure to be used in a projected study. During preliminary investigations of reactions of transition metal salts of organic acids, however, it was noticed that the solid residue from the thermal decomposition in vacuum, at about 500° C, of a ferric salt of mellitic acid gave an X-ray diffraction pattern characteristic of cementite. This communication is concerned with the use of this compound for the preparation of cementite. A detailed report of the kinetics of the thermal decomposition reaction will be published elsewhere⁴. Studies of the thermal decomposition of ferric salts of benzoic and of phthalic acids showed that no detectable cementite was present in the non-volatile crystalline products⁵.

For use in the preparation of cementite the ferric salt of mellitic acid was formed by heating two moles of ferric hydroxide with one mole of mellitic acid in a little water at 90° C for 30 min. The ferric hydroxide had been freshly precipitated from ferric chloride solution by the addition of ammonium hydroxide (both 'AnalaR'), boiled and washed by decantation six times. For the present study five preparations of ferric mellitate were investigated, in which the tan-coloured precipitates formed as above were treated as follows:

Sample *A*, filtered immediately after cooling, but not washed.

Samples *B1* and *B2*, washed by decantation; the precipitate remained tan coloured.

Samples *C1* and *C2*, the wet product washed with distilled water on the filter paper. Part of the product darkened, suggesting that some hydrolysis occurred.

Each batch of material was dried and the elements determined by combustion analyses. Iron was calculated from the weight of the residue from ignition in oxygen, which was assumed to be Fe_2O_3 only, and oxygen was found by difference. Results are shown in Table 1. The relatively large iron content of samples *C1* and *C2* is consistent with the foregoing view that some hydrolysis of the product has occurred, possibly yielding some ferric hydroxide.

Table 1. ANALYSES OF IRON SALT OF MELLITIC ACID

Sample	Fe	C	H	O
<i>A</i>	20.78	24.91	2.57	51.74
<i>B1</i>	20.45	24.61	2.53	52.41
<i>B2</i>	20.84	23.91	2.64	52.61
<i>C1</i>	23.51	24.05	2.48	49.93
<i>C2</i>	24.06	24.13	2.52	49.29

The non-volatile products remaining after thermal decomposition of samples of the foregoing salts between 470° and 500° C *in vacuo* or in contact with the gaseous products (excluding water) were pyrophoric, and considerable difficulty in handling was experienced. Products from decompositions between 450° and 470° C did not so readily oxidize in air. Decomposition of samples of salts *C1* and *C2* gave solid products which X-ray examination showed to contain appreciable amounts of Fe_2O_3 and/or Fe_3O_4 together with a diffuse pattern attributable to cementite.

Samples of preparations *A*, *B1* and *B2*, when decomposed for intervals between the limits 6 h at 460° C and 1 h at 500° C, gave cementite as the main crystalline product, but this was only observed for those samples in which atmospheric oxidation was prevented by chilling the solid to -195° C before admission of air to the apparatus, and subsequent storage under benzene. Samples for X-ray investigation were thoroughly mixed with a glue before evaporation of the benzene. Small traces of oxide were detected in the products from those reactions in which the gaseous decomposition products were allowed to remain in contact with the reactant during decomposition.

Samples of cementite, having X-ray diffraction patterns almost identical with a sample of cementite supplied by Dr. L. J. Dry of the S.A. Coal, Oil and Gas Corporation, Ltd., Republic of South Africa, were obtained by decomposition of 15 mg of sample *B1* and of 2 g of sample *B2* at 480° C with continual evacuation of products. Both samples were pyrophoric and an attempt was made to prevent atmospheric oxidation by the methods already described.

Determination of the surface area of the product cementite, from measurements of the adsorption of nitrogen at -195° C and application of the Brunauer-Emmett-Teller equation, showed that both sample *B1*, after decomposition 2 h 480° C with accumulation of gaseous products, and sample *A*, after decomposition 2 h 470° C with continual evacuation, had surface areas $240 \pm 10 \text{ m}^2 \text{ g}^{-1}$. Due to difficulties in handling in air we cannot be certain that no oxidation of these samples occurred, but both results show that a high surface area product is given.

The detailed mechanisms of the decomposition reactions are discussed elsewhere⁴, and only particular points arising from the results presented here will be considered:

(1) The decomposition product contains excess carbon; the composition is believed to be $\text{Fe}:\text{C}::1:2.6$. It is probable that a layer of finely divided carbon over the crystallite surfaces reduces sintering, so stabilizing the high-area product observed.

(2) The product from decomposition in the presence of gaseous oxides of carbon was indistinguishable from that observed from decomposition with continual evacuation. It seems probable, therefore, that the carbide was formed by the interaction of the finely divided iron-carbon mixture (the latter being the non-volatile product from the aromatic ring present in the acid radical) rather than a mechanism in which finely divided iron reacted with gaseous carbon monoxide.

(3) It is suggested⁴ that the decomposition of the ferric salt of mellitic acid 400°-500° C may involve reaction between a carbonaceous residue and an iron oxide. The foregoing results for samples *C1* and *C2*, where it is believed that ferric oxide was present in the reactant, suggest that the presence of this oxide may modify the course of the decomposition reaction to yield a product containing an appreciable amount of oxide. The mechanism described⁴, however, may be applicable to samples containing lower oxides of iron where ferric hydroxide was absent from the reactant.

Cementite may therefore be prepared by the method outlined here. Two disadvantages of the method are that the product contains excess carbon ($\text{Fe}:\text{C}::1:2.6$) and that the pyrophoric material is difficult to handle. Advantages of the method are that cementite may be prepared relatively rapidly at a low temperature (namely < 500° C) in a glass apparatus.

Oxidation of Some 2,4-Dinitrophenylamines with Ceric Salts

DURING an investigation into the mechanism of cerium-initiated graft polymerization of acrylic acid on to nylon, the behaviour of the dinitrophenylated product led us to examine the oxidation with ceric salts of some model 2,4-dinitrophenylamino-compounds. Since we are unable to complete the work, we are reporting the preliminary results, which may arouse interest elsewhere in the possible scope and mechanism of this reaction. The compounds examined were the potassium salts of DNP taurine (I, m.p. 249°-252° C) and 3-DNP-aminopropane sulphonic acid (II, m.p. 231°-233° C), the base (III, m.p. 71°-73° C) and its quaternary derivative (IV, m.p. 276°-277° C), obtained in 70 per cent yield by treatment of III with 1,3-propanesultone in boiling acetonitrile for 7 h; they all gave satisfactory analyses.

Oxidation at room temperature of each DNP-amine (0.01 g-mol) in water (50 ml.) or, for III, N sulphuric acid (50 ml.) with a solution of ceric ammonium sulphate (0.03 g-mol.) in N sulphuric acid (100 ml.) rapidly gave a yellow precipitate, which was isolated after 1 h and shown to be 2,4-dinitroaniline by comparison of its m.p. and infra-red spectrum with those of an authentic specimen. The yields were 95, 88, 75 and 70 per cent, respectively. Limiting the amount of oxidant to 1 mol per mol DNP-amine resulted in only an approximate halving

the yield of 2,4-dinitroaniline and no intermediate product was detected. Taurine did not reduce ceric ammonium sulphate significantly in 7 days at 25° C. Rates of oxidation at 25° C (Fig. 1) were determined by titrating the compounds (0.001 g/mol), dissolved in water with 0.001 N sulphuric acid (50 ml.), with ceric ammonium sulphate (0.005 g/mol) in N sulphuric acid (50 ml.) and titrating aliquots (10 ml.) of the reaction mixture with 0.005 N ferrous ammonium sulphate at suitable intervals. These curves indicate that the rapid primary oxidation of 2,4-dinitroaniline requires two equivalents of cerium, and if an analogy can be drawn with the oxidation of alcohols by ceric salts¹ or of alkylamides by perchlorates² one possible reaction path involves initial formation of a radical by abstraction of hydrogen at the carbon atom; disproportionation of this yields an amine, which is then hydrolysed. Alternatively the amine may result from direct attack of the radical by a second cerium ion:

Since the solutions were not de-aerated, routes involving oxidation of a peroxide derived from the initial radical and oxygen could also be implicated. Further, slow oxidation of the aldehyde would account for consumption of cerium beyond two equivalents.

Fig. 1. Oxidation of the 2,4-dinitrophenylamines I-IV with ceric ammonium sulphate at 25° C

The solutions obtained from oxidation of compounds I-III with 3 equivalents of ceric ammonium sulphate, after removal of dinitroaniline and cerium salts, on treatment with 2,4-dinitrophenylhydrazine in 5 N hydrochloric acid at 25° C yielded derivatives which, after recrystallization, melted with decomposition at 239°-244°, 202°-203° and 158°-159° respectively, and gave elemental analyses differing greatly from those of the expected aldehyde 2,4-dinitrophenylhydrazones. However, a concentrated solution from oxidation of compound (III) gave glyoxal bis-2,4-dinitrophenylhydrazone when boiled with the reagent in N hydrochloric acid, as did the authentic diethyl acetal of dimethylaminoacetaldehyde³, thus affording some confirmation that this aldehyde is a product of the oxidation.

We thank Dr. H. R. Cooper and Mr. B. F. Sagar for their advice.

BIOCHEMISTRY

Enzyme Regulatory Mechanisms at the Level of Lactate-oxidoreductase in Erythrocytes and Ascites Tumour Cells

In recent years several attempts have been made at a complete analysis of metabolic pathways. In comparing complex systems, be they intact cells or homogenates, with isolated enzymes, both similarities and differences¹⁻³ have been found. So far no single pathway has been completely elucidated with respect to its kinetics. For this reason we turned to the erythrocyte, as representing both structurally and metabolically one of the simplest biological systems. One line of research which is to be reported here was concerned with the regulation of glycolysis on the level of lactate oxidoreductase. These studies were extended to ascites tumour cells. In view of the generally high activity of the lactate oxidoreductase (LDH) it may be assumed that the lactate/pyruvate system is at equilibrium within the cell¹. Recently, however, deviations from the expected lactate/pyruvate ratios have been observed in brain homogenates³. We explored this question in a more detailed manner by studying the effect of pH on the formation of pyruvate and lactate.

The pH dependence of the lactate/pyruvate ratio. From the stoichiometry of the LDH reaction one would expect a pH dependence of the lactate/pyruvate ratio such that with increasing pH this ratio is diminished. Table I shows that the experimental results do not correspond to this assumption. As a matter of fact, in erythrocytes just the reverse is observed. For further study of these paradoxical observations the pH dependence of the lactate/pyruvate ratio of stroma-free dialysed haemolysates and of particle-free homogenates of ascites tumour cells was studied. The formation of pyruvate from added NAD and lactate was determined at varying pH values. The amounts of pyruvate observed were compared with calculated values based on the equilibrium constant of LDH. The results were the same as with intact cells. While there was approximate agreement between expected and experimental pyruvate formation at pH 8.4, twenty times the expected value of pyruvate was formed at pH 6.4. To explain these results we postulated the existence of an oxidation factor in erythrocytes and ascites tumour cells which disturbs the lactate/pyruvate equilibrium particularly at lower pH-values.

NADH₂- and NADPH₂-oxidases in erythrocytes and ascites tumour cells. Further experiments have indeed demonstrated, both in erythrocytes and in ascites tumour cells, extramitochondrial enzymes which oxidize NADH₂.

Table 1. LACTATE/PYRUVATE RATIO IN ERYTHROCYTES AND ASCITES TUMOUR CELLS

pH	10 ⁻³ moles/l.				Lactate/ Pyruvate

	Enzyme activity 10 ⁻³ moles/l.cells/min	
	NADH ₂	NADPH ₂
Human erythrocytes	0.102	0.177
Rabbit erythrocytes	0.113	0.099
Ascites tumour cells	0.017	0.018

The oxidases were measured spectrophotometrically at 340 nm, after 48 h dialysis in 0.1 M phosphate buffer, pH 6.4.

and NADPH₂ (Table 2). In Fig. 1 the pH-dependence of the erythrocyte oxidases is shown in a haemoglobin-free haemolysate of rabbit erythrocytes. It may be seen that both enzyme activities are optimal at pH 6.4. The NADH₂ oxidase activity is inhibited by higher concentrations of its substrate; with 1×10^{-4} M NADH₂ inhibition was practically complete. The inhibitory effect of NADPH₂ on its oxidase was much less pronounced. Under anaerobic conditions the oxidase activities were low whereas cyanide had no effect. From these observations it would appear that the oxidases are flavin enzymes. Formerly the existence of NADH₂- and NADPH₂-dehydrogenases (diaphorases) had been demonstrated in haemolysates¹¹. It might well be that the oxidases here described, and the dehydrogenases, are identical. On the other hand, it could be demonstrated that the oxidation of NADH₂ and NADPH₂ is mediated by at least two different enzymes. From the results in Table 3 it may be seen that a significant separation of the two activities could be obtained, so that a more than twenty-fold shift in the oxidase activity ratios of NADH₂ and NADPH₂ could be obtained. The two enzyme activities also differed in their stability towards lyophilization and dialysis, the NADPH₂ oxidase being the more sensitive. The dehydrogenase activities resembled the oxidases. The activity of these ratios was shifted about fifty-fold by the fractionation. The ratio of the oxidase to diaphorase activity was significantly higher with NADPH₂ as compared with NADH₂. Further purification of the enzymes is in progress.

The lactate-NADP-oxidoreductase in erythrocytes and in ascites tumour cells. The literature contains several reports concerning the reactivity of LDH of different tissues with NADP. With purified enzymes, various ratios of activity with NADP as compared with NAD have been reported, ranging from 0.003 to 0.05. In other communications the importance of this reaction for the generation of NADPH₂ for biosynthesis has been assessed^{4,5}. We have performed similar experiments on erythrocytes and ascites tumour cells. Table 4 summarizes the data from the literature together with our own results. It may be seen that erythrocytes have the highest activity with NADP which has been observed so far. The variation in the activity of the LDH with the two coenzymes led us to search for an NADP-specific LDH. In Table 5 are shown the results of a preliminary separation on DEAE cellulose. Whereas the original ratio of NAD/NADP activities in the dialysate of erythrocytes was 10:1, it increased to 60:1 in the first eluate and was only 1:2 in the second fraction.

Fig. 1. pH-dependence of NADH₂ (—) and NADPH₂ oxidase (---) in erythrocytes. 0.1 ml. of eluate (DEAE cellulose column) from stroma-free haemolysate from rabbit erythrocytes, 3.0 ml. of a 0.1 M phosphate buffer and 0.02 ml. of NADPH₂ solution, final concentration 5×10^{-3} moles per cuvette

In Fig. 2 are shown the pH optima of the two enzyme activities in erythrocytes. Whereas the main optimum of the NADP-dependent LDH is located at about pH 6, two optima were observed with NAD; the main optimum was at about pH 9.0 and a second one at about pH 5. In a dialysate of ascites tumour cells (Fig. 3), the pH optimum of the NADP-dependent LDH was also at pH 5.8–6.0 and that of the NAD-dependent enzyme at pH 8. It is conceivable that the acid pH-optimum represents an isoenzyme of the NAD-dependent LDH.

From these results it would appear that an NADP-dependent LDH occurs generally and accounts for the

* 1 oxidase unit = 10^{-3} moles/ml./min. 1 diaphorase unit = 10^{-4} moles/ml./min.

† The activity in the dialysate of the stroma-free haemolysate could not be measured because of the presence of haemoglobin. The haemoglobin was eluted from the column with 0.002 M phosphate buffer, pH 7.4, whereas fractions I and II were eluted with 0.2 M buffer at the same pH. Then Fraction I was lyophilized and dialysed again and the activity determined. Diaphorase activities were measured with dichlorophenolindophenol and K₃Fe(CN)₆ as acceptors.

ing activities with NADP reported in the literature. enzyme plays a definite part in the metabolic regulation of the cell. The importance of provision of NADPH₂ various reductive syntheses has been stressed⁴. The DP-dependent LDH is probably the specific mediator of the reduction of NADP by lactate. On the other hand, oxidation of NADPH₂ by pyruvate may also have a regulatory significance. Another aspect of its function is of a cross-link between the Embden-Meyerhof and oxidative pentose pathways.

Relating to the outset of our investigations, an explanation of the deviations of the lactate/pyruvate ratio from the theoretical values has been found in the activities of 2 types of enzymes: (1) the NADH₂ and NADPH₂ oxidases, and (2) the NADP-dependent LDH. In addition we have recently found an LDH which is independent of a pyridine nucleotide in ascites tumour cells⁶.

The effect of the oxidases is probably the more important one of the two. The oxidases represent part of the extramitochondrial oxygen uptake of the cells. For erythrocytes at least, their contribution may be of some importance at lower pH values.

Effect of Trans-Clutes on the Fluxes of Chloride Ions across Artificial Membranes

IN free diffusion across membranes the unidirectional fluxes of a solute are usually treated as mutually independent movements: each flux being a function only of the electrochemical potential of its solute in the compartment from which it originates (*cis* side). Across biological membranes, however, such as the gastric mucosa of the frog¹, or some cellular membranes²⁻⁴, the fluxes of various solutes strongly depend on the nature of the solutes on the *trans* side. These *trans* effects have been interpreted in terms of a carrier exchange mechanism with different affinity to different ions and molecules^{5,2}. In the present work such *trans* effects have been studied in artificial membranes, in which transport or exchange carriers can be excluded.

Commercial packing 'Celophane' or dialysing membranes were mounted between 'Lucite' chambers, as described earlier¹. In order to keep the experimental conditions comparable to those with the gastric mucosa of the frog, the *cis* side, to which the radioactive material was added, was bathed by (frog) Krebs bicarbonate ringer ('nutrient') solution (84.6 mM NaCl, 3.2 mM KCl, 1.8 mM CaCl₂, 0.8 mM KH₂PO₄, 0.8 mM MgSO₄, 17.8 mM NaHCO₃). For the control experiments the *trans* side was bathed with 'secretory' solution (102.1 mM NaCl, 4.3 mM KCl, 1.8 mM CaCl₂, 0.8 mM MgSO₄). In the test experiments the chloride of the *trans* solution was equivalently replaced by other anions. In the case of di- and tri-valent anions iso-osmolarity was restored by mannitol. In some experiments, all but 10.2 mM of the NaCl was replaced by iso-osmolar concentrations of non-electrolytes. Both solutions were bubbled by 5 per cent CO₂ and 95 per cent O₂. The unidirectional fluxes were measured with radioactive tracers as described elsewhere¹, and corrected for variations of self-absorption.

Contrary to the assumption of free diffusion the flux of chloride ions across artificial membranes decreased if the chloride ions of the *trans* side were replaced by heavier ions or molecules (Figs. 1 and 2). The effect seems to be an almost linear function of the cube root of the *trans* particle weight.

Fig. 1. *Trans* effect of anions on the Cl-flux across the short-circuited 'Cellophane' membrane. Composition of the solutions is given in the text. The *trans* ions are; 1, Cl; 2, formate; 3, HCO_3^- ; 4, NO_3^- ; 5, pyruvate; 6, SO_4^{2-} ; 7, I $^-$; 8, tartrate; 9, citrate. Room temperature. Correlation coefficient $r = 0.76$ ($P < 0.001$)

Fig. 2. *Trans* effect of non-electrolytes on the Cl-flux across the short-circuited 'Cellophane' membrane. Composition of the solutions is given in the text. The *trans* solutes used are indicated below. Room temperature. Correlation coefficient $r = -0.88$ ($P < 0.001$)

These *trans* effects are scarcely due to changes of the hydration of the membrane. Although dialysing membranes seem to take up slightly less water if the solute weight of the bathing solutions increases, these differences scarcely exceed 5 per cent of the control and may be still smaller if the *trans* solution, as in the flux experiments, bathes only one side of the membrane (Table 1). Furthermore, no correlation was found for a given *cis-trans* combination of solutes between the *trans* effect and the accidentally varying hydration of different membranes.

The *trans* effects cannot be accounted for by changes of viscosity within the membrane pores either, since the

Table 1. EFFECT OF VARIOUS ELECTROLYTES AND NON-ELECTROLYTES WATER CONTENT OF DIALYSING MEMBRANE

Bathing solution	No. membranes tested	H ₂ O content ml g ⁻¹ (dry weigh)
110 mM NaCl	3	1.26 ± 0.05
55 mM Na ₂ SO ₄ + 55 mM Mannitol	3	1.25 ± 0.04
55 mM Na ₂ Citrate	3	1.22 ± 0.06
220 mM Glycerol	4	1.30 ± 0.06
220 mM Mannitol	4	1.24 ± 0.03
220 mM Sucrose	4	1.21 ± 0.05

Pieces of dialysing membrane (No. 4465-A₂) were bathed for 1 h in solution at room temperature. The H₂O content was determined by weight before and after evaporation (at 105°) to dryness with a correction for so residues.

Table 2. EFFECT OF VARIOUS NON-ELECTROLYTES ON THE CONDUCTANCE OF 'CELLOPHANE' MEMBRANES FOR 10 mM NaCl

Bathing solution	2 sheets	Conductances 4 sheets mmhos per 0.785 cm ²	6 sheets
170 mM Glycerol + 10 mM NaCl	8.0 ± 0.3	4.1 ± 0	2.9 ±
170 mM Mannitol + 10 mM NaCl	8.0 ± 0.3	4.3 ± 0	2.9 ±
170 mM Sucrose + 10 mM NaCl	7.9 ± 0.2	4.1 ± 0	2.7 ±

All measurements were made at room temperature with three different membranes. In order to amplify the effects each membrane was made up of 2, 4 or 6 sheets of packing 'Cellophane'.

conductance of NaCl solutions decreased only slightly with increasing weight of added non-electrolyte molecule (Table 2).

According to Onsager's principles the flux of a given solute across the membrane may be altered by interaction with other fluxes, for example with the solvent flux or bulk flow⁶. Even between iso-osmolar solutions bulk flow might result if *cis* and *trans* solutes differ with respect either to the osmotic or the Stavermann deflection coefficient. The osmotic coefficients of the binary salts, as derived from the molar freezing point depressions, are rather close to those of NaCl⁷. Those of the non-electrolytes, however, very similar to each other, are all greater than that of NaCl, so that their effect on Cl-fluxes, if any, would be in the 'wrong' direction. The Stavermann coefficients, on the other hand, increase with the particle size⁸. Any bulk flow resulting from differences in these coefficients should be directed towards the side with the larger particles, that is, also in the 'wrong' direction. Hence by

Fig. 3. Effect of total solute concentration on *trans* effect of raffinose on the Cl-flux across the short-circuited 'Cellophane' membrane. On the *cis* side, NaCl in osmolar concentrations as indicated. On the *trans* side 10 mM NaCl and raffinose to complete iso-osmolarity with the *cis* side. Room temperature. Correlation coefficient $r = 0.81$ ($P < 0.01$)

with solute-solvent interaction cannot be the cause of observed *trans* effect.

solute-solute interaction, namely between Cl-ions and *trans* solutes within the membrane pores, seems improbable in view of the large pore radii, which are about 100 Å for dialysing tube and 40 Å for 'Cellophane'. Were it, however, effective, one would expect that the *trans* effect would also occur with non-ionic fluxes, and would increase with the total solute concentration. The *trans* effect on flux of ¹⁴C-urea caused by heavier molecules is almost negligible and may be accounted for by changes in membrane hydration or viscosity. On the other hand, the *trans* effect on Cl-ions does increase if the total solute concentration is raised on both sides of the membrane (Fig. 3). In summary, the observed *trans* effects cannot be attributed as yet to a single cause. Since they are negligible with non-ionic fluxes, the ionic pattern of the membrane may be important. Although the *trans* effects observed with urea mucosa are much greater than those with artificial membranes⁵, they clearly cannot be exclusively due to a simple transport or exchange mechanism, and to assume free diffusion for passive fluxes across any membrane is to be a dangerous over-simplification.

Identification of Dinitro-octylphenols in Certain Commercial Fungicides

A MIXTURE of nitrated alkylphenols is made by various manufacturers in the United States, Great Britain, and The Netherlands, who then esterify it with crotonic or other acids for the preparation of fungicides useful in the control of powdery mildews and also spider mites on various crops. Fractionation of this mixture, hereinafter called DNOP, on alumina (Spence type 'H') in benzene, followed by 2 per cent methanol in benzene, followed by 1 per cent acetic acid in 49 : 1 benzene-methanol, led to the isolation of three eluates¹. From each of these, amine salts were prepared and analyses showed them all to be of dinitro-octylphenols; the melting points, however, showed them to differ from each other and also from those of 2,4-dinitro-6-*n*-octylphenol and 2,6-dinitro-4-*n*-octylphenol². The melting points of salts of eluate II, which formed not more than 5 per cent of any of the DNOP samples, were close to those of the corresponding salts of dinocap phenol (4-dinitro-6-(1-methylheptyl)phenol)^{1,3}. As the biological activities (towards powdery mildews, spider mites, and test plants) of eluates I and II were similar, and those of eluate III were dissimilar, it appeared that eluate I, which formed about 60 per cent of one sample, was likely to be another isomer of dinocap phenol, and eluate III, which formed about 25 per cent of the same sample, an isomer of 2,6-dinitro-4-octylphenol other than the *n*-octyl or methylheptyl^{1,3}. The 1-ethylhexyl members of both series (2,4-dinitro-6-octylphenol and 2,6-dinitro-4-octylphenol) have therefore been synthesized, together with the

1-ethylpentyl and 1-ethylheptyl homologues, and the isomeric 2,6-dinitro-4-(1-propylpentyl)phenol. The ethyl-alkyl compounds were prepared by reaction of the appropriate alkyl magnesium bromide with *o*- or *p*-hydroxypropionophenone to give the *o*- or *p*-hydroxy-alkylphenol, respectively⁴. Dehydration by refluxing with toluene and a few crystals of iodine under a Dean and Stark tube yielded the alkene, which was reduced catalytically (palladium charcoal) at about 50° C under 500 lb./in.² pressure in 4-6 h to the 1-ethylalkylphenol. Nitration was done in glacial acetic acid, and the dinitro-(1-ethylalkyl)phenols isolated as various amine salts. Salts of the 2,4-dinitro-6-(1-ethylalkyl)phenols were easily recrystallized from benzene or methanol; those of the 2,6-dinitro-compounds required cyclohexene to give a tar-free product economically. The 2,4-dinitrophenols formed suitable salts with a greater range of amines than the 2,6-dinitrophenols. Melting points and analyses are given in Table 1.

‡ Forms salts with DOHA (m.p. 60° C) and *N*-ethylpiperidine (m.p. 90° C).

A comparison of the melting-points of the amine salts obtained from DNOP eluates with those of the salts of authentic dinitro-octylphenols (Table 2) led to the conclusion that eluate I was 2,4-dinitro-6-(1-ethylhexyl)phenol. Four of the five salts of eluate III had melting points agreeing well with those of the corresponding salts of 2,6-dinitro-4-(1-ethylhexyl)phenol, but there was a large discrepancy in the case of the morpholine salts.

* Eluate I also yielded salts with diamylamine, m.p. 39°-70° C, and 2-ethylpiperidine, m.p. 117° C.

To clear up the doubt about the identity of eluate III, nuclear magnetic resonance spectra in carbon tetrachloride of all three eluates, after purification via amine salts, were prepared by Mr. P. J. Ayres, Middlesex Hospital, and the band positions were computed and assigned by Dr. J. A. Elvidge, Imperial College of Science and Technology. Spectra were also prepared of the six dinitro-octylphenols, two *n*-octyl and four *s*-octyl, available at that time. Data obtained are given in τ values (and J c/s) in Tables 3 and 4. The inferences drawn are: (i) in spite of the discrepancy in the melting points of the morpholine salts, eluate III from the DNOP provided by Rohm and Haas Co. is 2,6-dinitro-4-(1-ethylhexyl)phenol; (ii) although the melting points of the piperidine salts of eluate III from May and Baker, Ltd., DNOP and of 2,6-dinitro-4-(1-ethylhexyl)phenol are so similar, the former was a mixture, approximately 1:1, of the latter and the isomer, 2,6-dinitro-4-(1-methylheptyl)phenol (a 1:1 mixture of the two

synthetic salts was found to melt at 118° C, so that there is no discrepancy here); (iii) the identities of eluates I and II, already deduced from the amine salts melting points, are confirmed.

The process used by the various firms manufacturing fungicides based on dinitro-octylphenols therefore produces not only the *para*-substituted phenol (as would be expected) but also causes the alkyl chain to add on to the benzene ring at an unexpected position in the chain, namely, at C₃. It has hitherto been assumed that addition of a chain derived from a 2-hydroxyalkane would take place at C₂.

We thank Mr. P. J. Ayres and Dr. J. A. Elvidge for the provision of evidence by NMR spectra, and May and Baker, Ltd., Murphy Chemical Co., Ltd., n.v. Philips-Duphar, and Rohm and Haas Co. for gifts of DNOP from their respective processes. We also thank Dr. D. Woodcock, Long Ashton Research Station, Bristol, for valuable help in the reduction of the alkenylphenols, and Dr. G. G. S. Dutton for advice on routes of synthesis.

n-Alkan-1-ols in Butter after Oxidative Deterioration

CHEMICAL mechanisms for the formation and decomposition of hydroperoxides in oxidizing lipids predict the presence of a wide range of compounds. Of these, three classes of aliphatic aldehydes (*n*-alkanals, *n*-alk-2-enals and *n*-alka-2,4-dienals) have long been isolated and identified and more recently the presence of non-conjugated unsaturated aldehydes (hex-*cis*-3-enal² and hept-*cis*-4-enal³), a vinyl ketone (oct-1-en-3-one⁴) and its corresponding alcohol (oct-1-en-3-ol^{5,6}) has also been demonstrated. The *n*-alkan-1-ols, also predicted by the mechanisms, had not hitherto been isolated and identified.

Experiments conducted in these laboratories have now shown that, in addition to oct-1-en-3-ol, *n*-alkan-1-ols are

also present in the steam distillate of oxidized but appreciable quantities (less than the *n*-alkanals but greater than the *n*-alk-2-enals) of the C_{1,2,5-8} and minor amounts of the C_{3,4} *n*-alkan-1-ols have been isolated from butter prepared from cream treated with copper and ascorbic acid.

The occurrence of *n*-alkan-1-ols in a degrading system has probably been overlooked as a result of the relative lack of flavour, their difficulty in characterization and the general acceptance that carbonyl compounds are the main contributors to the flavour of oxidized butter.

Work on the change in ratio of *n*-alkan-1-ols to aldehydes during low-temperature storage of butters will be reported in the *Journal of Dairy Research*.

Dependence of Photophosphorylation by Isolated Chloroplasts on the Oxidation-Reduction State of *N*-Methylphenazinium Methyl Sulphate (Phenazine Methosulphate)

It has been previously observed that the rate of photophosphorylation in chromatophores from photosynthetic bacteria was dependent on the oxidation-reduction state of phenazine methosulphate¹. On addition of ascorbic acid which reduces phenazine methosulphate non-enzymatically², the rate of photophosphorylation was observed to decrease markedly. However, ascorbate has been shown not to have any inhibitory effect on photophosphorylation in isolated chloroplasts catalysed by phenazine methosulphate³. Indeed, ascorbate is commonly used to stimulate photophosphorylation with phenazine methosulphate in isolated chloroplasts^{3,4}.

We have now made a systematic investigation of the effect of the oxidation-reduction state of phenazine methosulphate on photophosphorylation by isolated chloroplasts. The oxidation-reduction state of the system was controlled by using a TPNH-generating system and varying the effective reducing power by changing the concentration of added TPN. The experiments were conducted under strictly anaerobic conditions in the presence of a catalase-ethanol trap to remove traces of oxygen⁵.

Fig. 1 illustrates that phenazine methosulphate catalysed photophosphorylation is indeed dependent on the oxidation-reduction state of the electron carrier. Maximal rates of photophosphorylation were obtained in the presence of 1×10^{-5} M TPN. In the absence of TPN or in the presence of concentrations higher than 10^{-7} M the rate of photophosphorylation was markedly decreased. Measurement at 388 mμ (ref. 2) showed that the amount of oxidized phenazine methosulphate remaining after the reaction was completed was as follows: 75 per cent in the absence of TPN, 60 per cent with 1.3×10^{-5} M TPN (optimal) and 0 per cent at and beyond 1.3×10^{-5} M.

This direct demonstration of the dependence of the rate of photophosphorylation with phenazine methosulphate on the oxidation-reduction state of the system is in agreement with the conclusions of previous investigators using different experimental techniques. Thus, Jagendorf and Avron⁶ and Whatley⁷ concluded from the effects of *p*-chlorophenyl dimethylurea and oxygen that the oxidation-reduction potential of phenazine methosulphate was

PHYSIOLOGY

Monocular versus Binocular Visual Acuity

THIS communication describes experiments in which the threshold contrast of gratings viewed monocularly and binocularly have been determined (Fig. 1). We have modified the technique of Schade¹ so that a grating target, generated on an oscilloscope by supplying suitable signals to the x , y and z axes. It could be continuously varied both in contrast and fineness (spatial frequency) without the mean luminance of the screen changing. The energy distribution across the grating varied sinusoidally. The grating filled a rectangular area subtending 5° by 1.3° , and was surrounded by a circular field of 12° diameter of the same luminance as the oscilloscope screen (30 cd/m²). The screen was viewed from 57 in., and in all experiments particular care was taken to correct the eye to within 0.12 diopter with spectacle lenses.

To exclude possible artefacts due to fluctuations of accommodation² and pupil size, both eyes of one subject (D. G. G.) were fully accommodated. He viewed the screen through artificial pupils (2.8 mm diam.) placed close to the cornea. Special care was taken to centre the pupils^{3,4}. The non-viewing eye was covered with a piece of glass sufficiently frosted to obscure the details of the screen while presenting a field of similar luminance to that of the unobscured screen. The subject adjusted the contrast until he was satisfied that the grating could just be resolved. At each spatial frequency, threshold measurements were made with each eye and with both eyes together. The sequence of measurements was made in a random order.

The results are shown in Fig. 2. The general shape and magnitude of the contrast threshold confirm that

Fig. 1. The contrast of a grating the intensity of which varies with distance sinusoidally is defined as $\frac{I_{\max} - I_{\min}}{I_{\max} + I_{\min}}$. Three levels of contrast are shown: 1.0, 0.5 and 0.05. Note that as contrast varies the mean light level across the grating remains constant. The spatial frequency of a grating is the reciprocal of the angular distance between successive maxima in the sinusoidal intensity distribution. Spatial frequency is thus equivalent to visual acuity.

Fig. 2. The results from observer D. G. G. are plotted as contrast sensitivity on a log scale. Contrast sensitivity is defined as the reciprocal of the contrast at threshold. Contrast sensitivity = $\frac{I_{\max} + I_{\min}}{I_{\max} - I_{\min}}$. Spatial frequency in c/deg of visual angle is plotted on a linear scale. Each point is an average of two observations. The two straight lines are placed at a ratio of $\sqrt{2}$ apart in contrast and fitted to the results by eye. The interrupted lines are extrapolations to unit sensitivity (100 per cent contrast). In the upper portion of the figure the open circles represent the ratio, plotted on log scale, of binocular/mean-monocular sensitivity at each spatial frequency. The straight horizontal line corresponds to a ratio of $\sqrt{2}$.

found by Schade¹. It is clear that the threshold contrasts for the left and right eyes are very similar at all spatial frequencies. At each and every frequency the binocular threshold was found to be lower than that of the monocular threshold. That is, binocular sensitivity is greater than monocular.

Plotted along the top of Fig. 2 is the ratio of the binocular to the (arithmetic) mean monocular sensitivity at each observed frequency. A straight line has been drawn corresponding to a ratio of 1.414, that is, $\sqrt{2}$. The mean of the ratios in this experiment is 1.440 ± 0.030 S.E. The experiment was repeated on D. G. G., this time using natural pupils and accommodation, and the mean ratio was found to be 1.443 ± 0.032 S.E. For subject F. W. C., also with natural pupils and accommodation, the mean ratio obtained was 1.372 ± 0.045 S.E. The mean ratio for these three experiments, on two subjects, is 1.418 ± 0.021 S.E. None of these ratios differs significantly from $\sqrt{2}$.

The two parallel straight lines drawn through the results for frequencies higher than 6 c/deg are separated by a factor of $\sqrt{2}$ in contrast. The dotted extensions show extrapolations to unity contrast sensitivity; that is, the point where the grating is modulated from zero luminance to a peak level of twice the mean luminance. To avoid non-linearities in the responses of the oscilloscope phosphor, measurements were not made for contrasts higher than 0.4. It is estimated that at unity contrast the threshold frequency for monocular viewing would be 57.0 c/deg and for binocular viewing 61 c/deg. Thus, the calculated improvement in visual acuity for binocular viewing at high contrast would be $61/57.0 = 1.070$, that is, 7.0 per cent. Several workers have compared the visual acuity of one eye with two, using high contrast test objects, and have found values ranging from 5 to 10 per cent^{5,6}. However, they did not measure the ratio in the contrast domain, where we find improvements of the order of 42 per cent for binocular viewing at all spatial frequencies.

Our findings may be explained if it is assumed that when identical images are fed to two matched eyes their outputs are summed and that these outputs are noisy; that is, contain spurious extra components not correlated in each channel. Because the standard error of the sum of n independent measurements of a random or noisy process decreases as \sqrt{n} , an observer using two eyes can obtain two measurements which thus permit a $\sqrt{2}$ lower contrast to be detected.

It is interesting to consider the question of whether covering the other eye with a diffusing screen affects the threshold; the argument being that permitting an equal amount of light, containing no image detail, to reach the obscured eye would lower the contrast sensitivity of the viewing eye by introducing additional noise. To test the effect of the diffusing screen technique, a comparison was made with the effect of an opaque cover, using 30 c/deg as the test frequency for the viewing eye. It was found that the mean ratio of contrast sensitivity for diffuse/obscured presentation to the non-viewing eye was 1.019 ± 0.022 S.E. As this mean does not differ significantly from a ratio of 1, it suggests that it makes no difference whether no light, or a diffuse light, enters the non-viewing eye, providing the pupil size of the viewing eye is fixed.

The fact that a stimulus that should have only added noise does not raise the threshold could be interpreted as evidence against a simple hypothesis of signal-to-noise detection. However, it may be that complete addition of signal and noise occurs only when congruent images are presented to the two retinæ.

Lythgoe and Phillips⁷ and Crozier and Holway⁸ compared monocular with binocular luminance thresholds for a patch of light exposed for 0.2 sec; they similarly found that the ratio of the binocular to the average of the monocular thresholds was equal to $\sqrt{2}$. These workers

explain their results in terms of Piper's law, which states that the threshold is inversely proportional to the square root of the area of the test field. It is difficult to account for our findings in terms of an area-threshold relationship.

Pirenne⁹, who has also measured binocular and monocular absolute thresholds, finds an improvement of a factor of 1.25. As he clearly illustrates, this improvement can be explained by probability summation between independent channels without invoking the physiological summation of signals from the two eyes; a class of argument which must be distinguished from our own which requires the actual physical summation of signals from the two eyes. Recent electrophysiological evidence seems to provide a basis for such physiological summation. Furthermore, a description in terms of the detection signals in the presence of noise seems to offer a more general explanation^{11,12} which can encompass the improvement found under such widely differing binocular viewing conditions.

The effect of doubling the signal luminance and presenting it to one eye was next tested. This was done by measuring the contrast sensitivity for identical fields differing only by a factor of 2 in luminance. The field was viewed by D. G. G. through a 2.8 mm-diam. pupil with his atropinized right eye. Ten measurements of threshold were made at each luminance (40 and 80 cd/m²) for a grating of 30 c/deg. The mean ratio of the contrast sensitivity for the higher/lower luminance was found to be 1.173 ± 0.028 S.E. This mean ratio differs significantly from 1, and also from 1.440 ± 0.030 S.E. found for the same subject viewing the field with both eyes through pupils of 2.8 mm. This result indicates that we are observing at a luminance (80 cd/m²) sufficiently high to be on the 'plateau' where visual acuity is substantially independent of luminance¹³. Thus, at these luminance levels it is advantageous to use a binocular eyepiece for microscopy for contrast sensitivity is improved, even binocular viewing is achieved by splitting the light into two portions each of half the intensity.

One of us (D. G. G.) is supported by a U.S. National Science Foundation post-doctoral fellowship. This investigation was supported by a U.S. Public Health Service research grant (NB 05046-01) and a grant from the W. H. Ross Foundation (Scotland).

A Central Action of Hemicholinium

THE action of hemicholinium No. 3 (α - α -dimethyl ethanolamine 4,4'-bisacetophenone, HC 3) on the synaptic release of acetylcholine at the neuromuscular junction and within autonomic ganglia is well established¹. However, apart from the finding that intravenously administered HC 3 reduces the acetylcholine content of the pons and medulla of dogs², and the report that locally administered HC 3 reduces the content and synthesis of acetylcholine within the caudate nucleus of rats³, there

yet no evidence that this substance affects the output of acetylcholine from central cholinergic synaptic terminals. There is convincing evidence that acetylcholine is the excitatory transmitter released from the axon lateral endings on Renshaw cells of the feline spinal cord⁴, and the opportunity was taken to assess the action of HC 3 at these synapses.

The experiments were performed in the lumbar segments of spinal cats anaesthetized with pentobarbital sodium. Renshaw cells were activated synaptically by pulses in the appropriate segmental ventral or dorsal roots, and extracellular spike potentials (negative-positive, 100–1,000 μ V in amplitude) were recorded by the diaphragm chloride-containing centre barrel of five barrel micropipettes⁵. The overall diameter of these micropipettes was 4–6 μ , and the other barrels contained aqueous solutions of acetylcholine bromide (1 M); DL-homocysteic acid (sodium salt, 0.2 M, pH 7.5); HC 3 bromide (0.1 M); triethylcholine chloride (0.1 M) or diaphragm chloride (M), from which pharmacologically active substances could be ejected by suitably directed electrophoretic currents⁶. The orthodromically evoked spikes were counted by means of a gated electronic counter, and the responses were also photographed for accurate measurement of latencies.

Control experiments established that although there was some reduction in the number of spikes evoked by prolonged maximal ventral root stimulation at frequencies of 3–10/sec, the number was reasonably stable after the first 5–10 min for a period of at least several hours. In particular there was no appreciable increase in the latency of the first spike. During the electrophoretic administration of HC 3 (5–20 n. amp) there was an increase in the latency of this and subsequent spikes, and often a marked reduction in the total number of spikes. These alterations in firing pattern were first noticed 10–20 min after the beginning of the HC 3 administration and were progressive: in all cases the ventral root was stimulated continuously at the foregoing frequencies. Alterations in the total number of spikes were complicated by a reduction in the sensitivity of some cells to electrophoretically administered acetylcholine, and by actual excitation by the HC 3, as revealed by a facilitation of firing induced by DL-homocysteic acid with or without an actual increase in the 'spontaneous' discharge rate. Excitation by HC 3 was characterized by periodic bursts of high-frequency firing similar to those produced by gallamine and D-tubocurarine⁷; often such a burst followed the delayed first synaptic spike (Fig. 1, B, lower record). These effects, presumably due to a direct interaction of HC 3 with

postsynaptic structures¹, were usually maximal within a few minutes of the administration of this agent and could be minimized to some extent by using extremely low electrophoretic ejection currents (less than 10 n. amp).

The most marked effect of HC 3 was an increase in the central latency of the first spike evoked by a supramaximal ventral root stimulus, as illustrated in Fig. 1, and in several instances prolongation of this time beyond 2–4 msec was followed by complete block of synaptic excitation approximately 60–80 min after the beginning of the HC 3 administration. Partial recovery was observed in several instances within 5–10 min of the cessation of the HC 3 administration (Fig. 1, D). As dihydro- β -erythroidine, a powerful antagonist of the nicotinic receptors of Renshaw cells⁴, has little or no effect on the latency of the first spike evoked by such a stimulus, it is unlikely that the increase of latency produced by HC 3 is the result of a postsynaptic action, particularly as increases were observed when the actual sensitivity of Renshaw cells to acetylcholine was undiminished. Hence it may be reasonably proposed that in the presence of HC 3 the output of acetylcholine per stimulus becomes diminished, with a consequent reduction in the rate of rise of the resultant excitatory postsynaptic potential. Two factors may be involved in the time over which it was necessary to stimulate the ventral root repetitively before such a presynaptic action could be demonstrated: the presynaptic store of acetylcholine is evidently comparatively large compared with the amount released per impulse, and a maximum ventral root stimulus normally results in the release of a large amount of acetylcholine in the environment of a particular cell compared with the amount necessary to produce an above-threshold postsynaptic depolarization.

Renshaw cells may also be fired synaptically by dorsal root volleys without the involvement of motoneurons⁷. Not all cells responded to such afferent excitation, and many did not follow repetitive stimulation (3–10/sec) of the dorsal root, presumably because of the polysynaptic nature of the excitatory pathway. However, in one case, conditions were satisfactory and the responses of this cell to dorsal root stimuli at a frequency of 3.3/sec were unaltered after 60 min administration of HC 3, at which time the latency of the first ventral root-induced spike had been increased from less than 1 msec to approximately 2.8 msec. This finding confirms other pharmacological evidence that the firing of Renshaw cells by dorsal root afferent volleys may not involve cholinergic mechanisms⁷, and also suggests that the presynaptic action of HC 3 may be specific for cholinergic terminals. Additional evidence for this latter proposal was the finding that prolonged administration of HC 3 failed to influence the synaptic excitation of dorsal horn interneurons, which are presumably not innervated by cholinergic fibres⁷.

Experiments were also carried out on Renshaw cells using triethyl(2-hydroxyethyl)ammonium (triethylcholine); but the use of this agent was complicated by a marked depressant action on the sensitivity of the cells to acetylcholine, and a strong excitant action similar to that observed with HC 3. Attempts were made to influence the synaptic firing of Renshaw cells by inhibition of choline acetylase, using electrophoretically administered fluoracetate, *p*-chloromercuribenzoate or diphenyllethylacetic acid⁸. These experiments were unsuccessful, possibly because of the failure to obtain a sufficiently high concentration of the inhibitors at the site of acetylcholine synthesis. Intravenously administered HC 3 (10 mg/kg) was also ineffective, probably for the same reason.

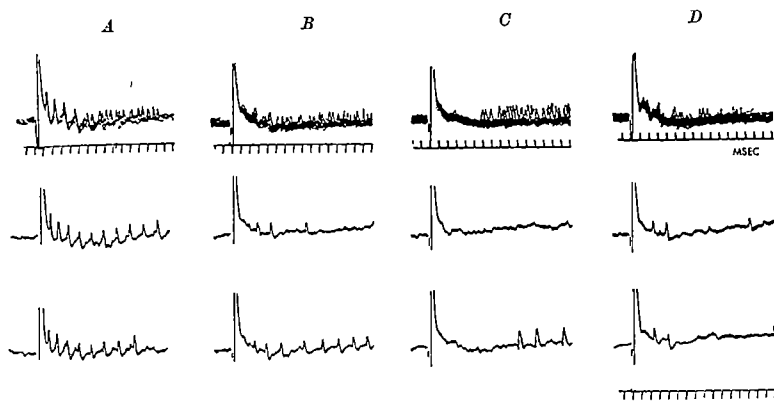

Fig. 1 Spike responses of a single Renshaw cell (upper records—approximately 20 superimposed tracings at a frequency of 5/sec; lower records—single tracings); (A) before, (B) at 31 min and (C) 61 min during, and (D) 3 min after the electrophoretic ejection of HC 3 for 69 min (10 n. amp for 59 min, 40 n. amp for 10 min). The measured latencies of the first spike are (A) 1.21 msec; (B) 2.42 msec; (C) 5.8 msec and (D) 1.9 msec from the ventral root stimulus. In many of the records of (C) the neurone failed to respond to ventral root stimulation and the latency was measured from the superimposed tracing. The sensitivity of this cell to acetylcholine and DL-homocysteic acid was enhanced by HC 3. The ventral root was stimulated supramaximally at a frequency of 5/sec throughout the series, and had been so stimulated continuously for approximately 1 h beforehand. Time, msec for all records. The spikes were approximately 300 μ V in amplitude.

In conclusion HC 3, which presumably prevents the transfer of choline into central presynaptic cholinergic terminals, thus limiting the rate of acetylcholine synthesis¹, is suitable for testing the cholinergic nature of central synapses, provided the appropriate pathway is activated sufficiently to exhaust the transmitter stored within the endings.

We thank Prof. R. Paoletti for a supply of diphenyl-ylethylacetic acid.

HAEMATOTOLOGY

Kinetic Differences between Human Red Cell and Leucocyte Pyruvate Kinase

WITHIN the group of non-spherocytic haemolytic anaemias classified as 'type 11' by Selwyn and Dacie¹, Valentine, Tanaka and Miwa² found a specific erythrocyte deficiency of pyruvate kinase (PK). The leucocyte PK activity in patients with this disease is normal², suggesting that the genetic control of leucocyte PK differs from that of red cell PK. Electrophoretic differences among PK preparations from rat kidney, liver, cardiac muscle, brain and skeletal muscle were reported by Fellenberg *et al.*³. Chromatographic, electrophoretic, solubility and structural differences between the normal human leucocyte and red cell PK have been presented⁴.

Pyruvate kinase catalyses the conversion of phosphoenolpyruvate (PEP) and ADP to pyruvate and ATP. Boyer⁵ has reviewed studies of enzyme kinetics for rabbit muscle PK. He concludes that phosphoryl transfer occurs by a direct transfer of the phosphoryl group from the donor to the acceptor substrate; that there is one binding site on PK for ATP and ADP and another site for pyruvate or PEP; and that in the forward reaction non-compulsory or independent combination with ADP or PEP occurs with 'equilibrium kinetics' applying. This report describes an investigation of the kinetics of human red cell and leucocyte PK purified by methods previously described⁴. We observed properties for the human leucocyte PK identical to those described for rabbit muscle enzyme. The Michaelis constant (Fig. 1) observed for each substrate is independent of the concentration of the second substrate. The K_m values for PEP of 1.0×10^{-4} M, and for ADP of 1.78×10^{-4} M, are very similar to the values reported⁶ for the rabbit muscle preparation. The relation between the general kinetic coefficients, $\frac{\Phi_1 \times \Phi_2}{\Phi_{12}} = \Phi_0$ according to

Dalziel⁷, is compatible with a mechanism of random addition of substrates in which the combination of the enzyme with one substrate does not influence its affinity for the second substrate.

The red cell enzyme has different kinetic properties. At least ten-fold higher concentrations of PEP are required, and apparent Michaelis constants for each substrate vary with the concentration of the second substrate (Fig. 2).

Initial velocities measured in the presence of one of products, ATP, obey the general equation:

$$\frac{(E_0)}{v} = \Phi_0 + \frac{\Phi_1}{(\text{PEP})} \left[1 + \frac{(\text{ATP})}{K_{\text{ATP}}} \right] + \frac{\Phi_2}{(\text{ADP})} + \frac{\Phi_{12}}{(\text{PEP})(\text{ADP})} \left[1 + \frac{(\text{ATP})}{K_{\text{ATP}}} \right]$$

These findings suggest competitive inhibition of ATP-PEP with an inhibition constant, K_{ATP} , of 3.5×10^{-4} . Only an ordered binding of substrates will account these results. Because of the assay system used, we have not yet studied the reverse reaction, nor the effect of pyruvate on initial velocities of the forward reaction. These reasons, we cannot be more specific about the mechanism for the red cell enzyme⁸.

The demonstrated differences in chemical⁴ and kinetic properties of erythrocyte and leucocyte PK support known difference in genetic control² of this enzyme. Evaluation of kinetic differences between normal and mutant erythrocyte enzyme, however, must take into account the more complicated mechanism of action of erythrocyte PK. Waller and Lohr⁹ have reported a high Michaelis constant of red cell PK for PEP in patients with pyruvate kinase deficiency. Three unrelated patients whom we have studied the kinetics of purified red cell enzyme showed no difference from normal for both substrates.

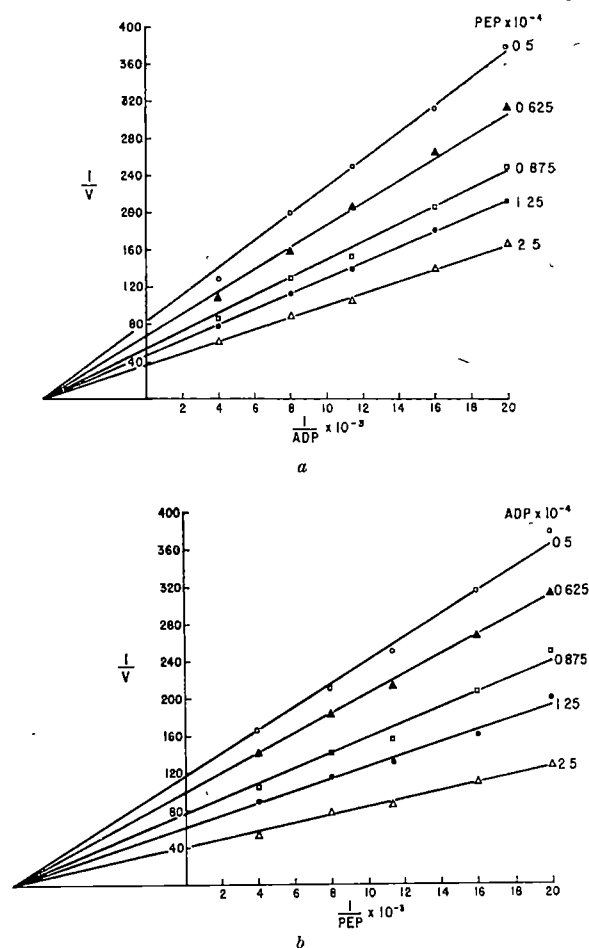

Fig. 1. (a) Effect of ADP on the velocity of the leucocyte PK reaction at various PEP concentrations. Assays were made at 37° C in a total volume of 3.0 ml. with 0.075 M K⁺; 0.016 M Mg⁺⁺; 0.008 M triethanolamine HCl at pH 7.4, and PEP at 0.5; 0.625; 0.875; 1.25 and 2.5 $\times 10^{-4}$ M. The initial velocity is in micromoles of DPNH oxidized per min (method of Bücher and Pfleiderer¹⁰). Intersection at the negative abscissa gives an estimate for K_{ADP} of 1.78×10^{-4} M. (b) Effect of PEP on the velocity of the leucocyte PK reaction at 0.5; 0.625; 0.875; 1.25 and 2.5 $\times 10^{-4}$ M ADP concentrations. Conditions were the same as above. Estimate for K_{PEP} of 1×10^{-4} M.

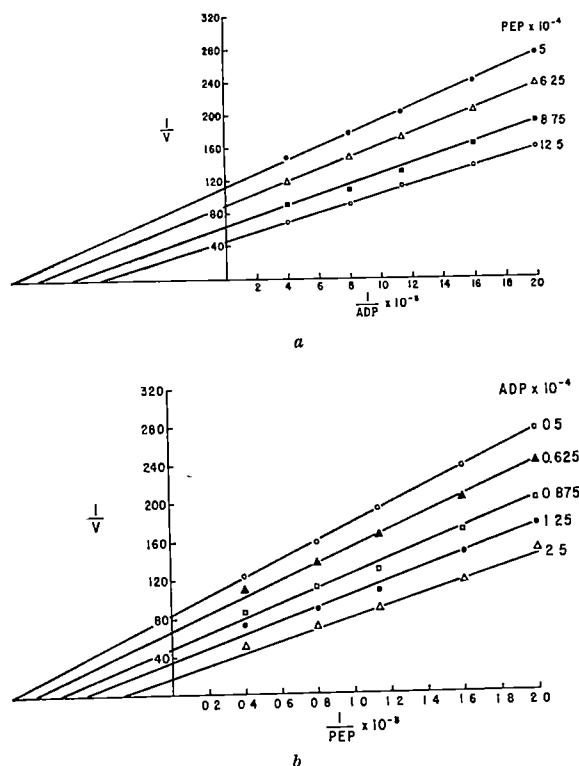

Fig. 2. (a) Effect of ADP on the velocity of the red cell PK reaction at 5; 6.25; 8.75 and 12.5×10^{-4} M PEP concentrations. Conditions were the same as in Fig. 1. (b) Effect of PEP on the velocity of the red cell PK reaction at 0.5; 0.625; 0.875; 1.25 and 2.5×10^{-3} M ADP concentrations. Conditions were the same as in Fig. 1.

strates. This would suggest a control gene mutation involved in this disease.

Inhibition of Haemolysis by 'Cremophor' in Conserved Blood

THE biological value of conserved blood is determined by the erythrocyte survival time after re-infusion which, after storage for 3-4 weeks, is so low as to prohibit further use of the erythrocytes. The plasma, however, may be used for several other purposes if it is not too haemolytic. After a lapse of about the same time the haemolysis rate increases remarkably so that blood banks are often

obliged to discard whole-blood conserves after the date of expiration.

Claims have been made that vitamin E possesses haemolysis-inhibiting properties in blood banks¹⁻⁵. In an attempt to verify this quality of vitamin E and to elucidate its mechanism of action we added solutions of tocopherol acetate (50 mg/ml.) in a ratio of 2 per cent v/v to ACD-blood. As an emulgator of the water-insoluble vitamin E, these solutions contained 'Cremophor EL'* (manufactured by Badische Anilin- u. Sodafabrik AG., Ludwigshafen) in concentrations varying between 40 and 200 mg/ml. Appropriate controls were run with 'Cremophor EL' only. These banks were judged visually as to haemolysis after a storage time of 40-80 days. Haemoglobin determinations were carried out in the supernatant ACD-plasma after centrifugation. The results showed, much to our surprise, that 'Cremophor EL' alone has a haemolysis-inhibiting effect far exceeding a rather questionable effect of vitamin E. The plasma of ACD-blood to which solutions of 40-200 mg/ml. 'Cremophor EL' had been added (final concentration 0.8-4 mg/ml.) remained perfectly clear after a storage time of 40-80 days and contained no appreciable amounts of haemoglobin, whereas the ACD controls were severely haemolytic. Indeed, the addition of vitamin E in low concentration ranges of 'Cremophor EL' seemed to block even the 'Cremophor EL' action. It seems possible that the surface activity of 'Cremophor EL', exhausted by vitamin E in the investigations with low concentrations of 'Cremophor EL', represents the key to the mode of action. Investigation of the activity of other surface-active agents seems therefore indicated. From the technical point of view the haemolysis of ACD-blood can be virtually abolished by addition of 'Cremophor EL', up to a storage time of about 80 days (perhaps even longer).

It remains an open question whether, in the papers cited here, surface-active agents have interfered, as few data concerning controls with such substances are mentioned. However, from the data given in refs. 2, 3 and 5 it can be concluded that 'Cremophor EL' has been used as an emulgator.

RADIOBIOLOGY

Uptake by Plants of Radiostrontium from Contaminated Soils

IN a recent report from this department¹ it was shown that the extractability of radiostrontium from contaminated soil samples was effectively reduced by heat treatment and by the addition of phosphate to the soil. It was pointed out that, under emergency conditions, heat-treatment of the contaminated soil surface and heavy phosphate application might thus reduce the uptake by plants of radiostrontium more efficiently than liming, which is only effective in soils of low calcium status. In the investigation reviewed here the influence of heat treatment and superphosphate application on the plant uptake of radiostrontium was examined in pot experiments. For comparison the effect of applying calcium carbonate to the contaminated soil surface was also determined.

Spring barley (variety 'Pallas') was grown to maturity in PVC pots, each containing 22 kg of soil. Two loamy and

Table 1. ANALYSIS OF SOIL

Locality	Soil type	pH in water	Cation-exchange capacity (m. equiv./100 g)	Exchangeable Ca ⁺⁺ (m. equiv./100 g)	Ca-saturation (%)	Organic matter (%)
Blangstedgaard	Loamy	7.6	15.2	12.6	83	2.2
Ødum	Loamy	7.0	9.2	6.1	66	1.6
St. Jyndeved	Sandy	6.5	11.1	3.9	35	2.4
Borris	Sandy	6.4	10.5	3.7	35	1.9

two sandy soils were used (Table 1). 11 kg of soil was put into each pot, and 40 µc. of carrier-free ⁸⁹Sr in 20 ml. of water was sprayed evenly over the surface before the superphosphate and calcium carbonate were added. For the heat treatment the contamination was performed by adding the carrier-free ⁸⁹Sr to 160-g samples of soil, which were then air-dried and heated to the desired temperature for 10 min. The contaminated sample was evenly distributed over the surface of the 11 kg of soil in the pot. The additional 11 kg was then added, and the seeds were sown. It was attempted with this experimental technique to imitate a surface contamination followed by treatments and ploughing. The following treatments were examined:

Control: 40 µc. ⁸⁹Sr per pot.
 T-500: 40 µc. ⁸⁹Sr and heating to 500° C
 T-800: 40 µc. ⁸⁹Sr and heating to 800° C.
 P-1: 40 µc. ⁸⁹Sr + 10 g superphosphate (equiv. to 2 tons/ha).
 P-2: 40 µc. ⁸⁹Sr + 20 g superphosphate (4 tons/ha).
 Ca-P: 40 µc. ⁸⁹Sr + 75 g CaCO₃ + 20 g superphosphate (15 and 4 tons/ha resp.).
 Ca-1: 40 µc. ⁸⁹Sr + 37.5 g CaCO₃ (7.5 tons/ha).
 Ca-2: 40 µc. ⁸⁹Sr + 75 g CaCO₃ (15 tons/ha).

The concentration of ⁸⁹Sr in grain and straw is given in Table 2.

Table 2. THE CONCENTRATION OF STRONTIUM-89 IN BARLEY GROWN IN FOUR CONTAMINATED SOIL TYPES IN POT EXPERIMENTS

Heating the contaminated soil to 800° C reduced the uptake of radiostromium by plants from loamy soils by a factor of twenty. In the sandy soils only a four-fold decrease in the uptake was found. The difference between loamy and sandy soils is greater than expected from the extractability investigations¹; but this might be ascribed to differences in the mineral composition of the soils used. The fixation of radiostromium is probably caused by an alteration of the clay minerals at high temperatures. The results indicate that a very effective reduction in the uptake from loamy soils can be obtained by heating the contaminated soil surface; but the practical application of this method is complicated by the high temperatures needed.

Addition of superphosphate caused a marked reduction in the plant uptake of radiostromium. The largest amount—equivalent to 4,000 kg per hectare—resulted in a four-fold decrease in the strontium-89 uptake from the sandy soils; in the loamy soils the reduction factor was three. It is known from fertilizer experiments that the plants utilize only a small part of the phosphorus added in superphosphate. The remaining portion is converted into phosphate compounds of lower solubility, for example, dicalcium phosphate, octacalcium phosphate and hydroxyapatites. It seems reasonable to expect that a co-precipitation of slightly soluble calcium-strontium phosphate would occur in contaminated soils if sufficient amounts of phosphate were added. However, most of the previous experiments on the effects of phosphate application to contaminated soils²⁻⁴ have shown only a small reduction in the plant uptake of radiostromium. Although Uhler⁵ used massive amounts of ammonium phosphate

(phosphorus content equivalent to that in 28.5 tons superphosphate/ha), the uptake from a calcareous soil was only reduced by 50 per cent, and no effect was seen on acid soil. The radiostromium and phosphates were usually mixed into the entire rooting medium, and consequently the phosphate concentration may have been too low to cause precipitation. In the present investigation a high concentration of phosphate in close contact with strontium-89 was assured by applying the superphosphate directly to the contaminated soil surface. The results obtained by means of this technique could be interpreted as increased precipitation of strontium in the form of slightly soluble phosphates, and thus a reduced plant availability. Addition of calcium carbonate together with the superphosphate decreased the effect as compared with superphosphate alone.

Addition of calcium carbonate did not reduce the uptake of radiostromium from these soils. On the contrary, the results indicate a slight increase in the uptake, even from the sandy soils of relatively low calcium saturation. The high concentration of calcium carbonate in intimate contact with the contaminated soil layer has apparently caused an increased plant availability of the radiostromium. This is in agreement with the solubility characteristics reported by Schroeder *et al.*⁶ and the suggestion by Wiklander⁷ that heavy application of lime might lead to increased solubility of strontium.

Preliminary results from a similar—but long-term experiment with the same four soils in microplots in the field show the same tendencies as the results of the present experiment reported here.

Mechanism of Uptake of Trace Elements by Plant Roots

It is well known that chemical elements can be concentrated in very large factors by plant cells, that is to say, the final concentrations in the cells may exceed those in the media by many orders of magnitude. Enrichment is often observed not only for elements that are essential to the plants, but also for elements not known to be essential and even sometimes for elements that normally do not occur to any extent in plants.

The question thus arises as to what mechanism is responsible for the elements being taken up against concentration gradients. In the case of some major nutrients accumulation is due to 'active transport', that is, the required osmotic work is done at the expense of metabolic free energy. For example, much of the uptake of potassium is due either to its own active transport or to a potential difference set up in the active transport of another ion¹. However, so far as we are aware the importance of active transport does not appear to have been demonstrated for the accumulation of 'trace elements', here to be defined as elements needed by plants only in minute quantities, or not needed at all.

The nature of the mechanism responsible for the accumulation of trace elements is of basic importance to agriculture and also to the evaluation of hazards due to

ionuclides, especially from nuclear explosions (fall-out) from nuclear reactors. Therefore, following up preliminary experiments with unicellular algae (*Chlorella*)², have studied the uptake of zinc, an essential element, roots of a crop plant.

We used barley plants that had been grown for about days in tap water. The roots were about 10 cm long; they were cut from the plants 4 h before the start of the experiments and washed several times with distilled water. Normally 1–2 g of roots were shaken with 10 ml. a solution of radiozinc (zinc-65; half-life 245 days), and aerated, for a few hours. The uptake was computed from the remaining activity of the solutions, as measured with a Geiger liquid counter after removal of the roots. For comparison, analogous experiments were performed using radiopotassium (potassium-42; half-life 5 h). In a few experiments, longer-lived rubidium-86 (3.7 days) was substituted for potassium; it is well known that rubidium and potassium behave similarly in respect of uptake³. Occasionally, experiments were repeated without severing the roots from the green parts, but the results were not very different. The enrichment factor defined as the ratio of the concentration in tissue (roots) to that in the supernatant for zinc was high—about 10^4 in the case of zinc concentrations of the order 10^{-7} M in the supernatant—and depended on experimental conditions. However, the mechanism of enrichment is clearly quite different from that for potassium.

(1) Equilibrium of zinc between roots and solution was reached within a few minutes while uptake of potassium continued for much longer periods. (2) The 'decoupling' metabolic poison dinitrophenol (DNP), in concentrations up to 10^{-2} molar (M), had no influence on the uptake of zinc, while the uptake of potassium was depressed to less than 10 per cent of the normal value; similar results were also obtained with sodium azide. (3) After the roots had been killed by treatment with alcohol for 10 min, the uptake of potassium was practically zero, while that of zinc increased by 50–100 per cent. (4) After root tissue had been homogenized by grinding with glass, the uptake of potassium was almost completely suppressed, but that of zinc again increased two-fold. (5) While the uptake of potassium was not influenced by most foreign ions, for example, sodium or magnesium, in moderate concentrations (up to 10^{-2} M), foreign ions generally competed strongly with zinc: for example, the elements lanthanum, cerium, calcium, magnesium, cobalt, manganese, strontium and barium displaced radiozinc with efficiencies decreasing in that order, namely 138–35 per cent as strongly as active zinc of equal (2×10^{-4}) molarity. (6) At least in the range 0°–20° C, and during a period of 5 h, the temperature coefficient for the uptake of radiozinc by intact roots was very much (about a factor of 10) smaller than that for the uptake of radiorubidium.

We suggest that the accumulation of zinc by the plants is due to passive processes, not dependent on metabolism or the integrity of the cells, namely, to exchange adsorption and compound formation⁴. Processes not linked with metabolism are, of course, also observed with potassium^{3,5}, but in experiments over longer periods active processes predominate.

BIOLOGY

Prolactin and the Incidence of Brood Patch Formation and Incubation Behaviour of the Two Sexes in Certain Birds with Special Reference to Phalaropes

It has been demonstrated experimentally that brood patch formation in certain passerine birds (in which typically, only the females develop brood patches and incubate in Nature) depends on oestrogen and prolactin action¹.

In the phalaropes (a sub-family of three species only, two holarctic, one Wilson's (*Steganopus tricolor*), nearctic) only males incubate and only they form brood patches. Johns and Pfeiffer² showed experimentally that the hormonal stimuli for brood patch formation in two species of phalaropes (one of which was Wilson's) are an androgen and prolactin.

One of us has made a preliminary publication³ citing data on the gonadal concentrations of the principal sex hormones of breeding Wilson's phalaropes in comparison with those of some other birds. He does not now altogether accept the interpretation given³ to these data, but the results reported show that female phalaropes are not deficient but rather 'high' in gonadal androgens and hence are unlikely to be poor androgen secretors. Therefore their failure to form brood patches might depend on a deficiency of prolactin, rather than a lack of androgen production.

This communication reports the results of experiments with: implants of the pituitaries of Wilson's phalaropes or Killdeer plovers (*Charadrius vociferus*) on the crop sac of common domestic pigeons by the technique described elsewhere¹; or with intradermal injections of pituitary extract-suspensions over the crop sac, followed in both cases by the technique of examination previously outlined by one of us⁴. Table 1 summarizes the results obtained. Although in no case did we obtain a full-blown crop sac development with up to 10% of prolactin (ovine supplied by the Endocrinology Study Section, U.S. National Institutes of Health) or with our avian materials, the data show that breeding male phalaropes produce some prolactin and females significantly less or none. Our two tests on Killdeer material permit no conclusion, but they are compatible with the view that since both sexes of this bird develop brood patches both may form prolactin.

Supporting evidence comes from the data on relative pituitary weight of breeding season Wilson's phalaropes, red-winged blackbirds (*Agelaius phoeniceus*) and of Killdeer which are summarized in Table 2. It should be noted that one of us has previously demonstrated the presence of prolactin in female (males were not tested) red-winged blackbird pituitaries⁵.

We can see no obvious *a priori* reasons for sexual differences in adeno-hypophyseal function in breeding birds of the three representative species examined, other than relative differences in prolactin production. We believe

Table 1. PIGEON CROP SAC TESTS FOR PROLACTIN, USING IMPLANTS (I) OR INTRADERMAL INJECTIONS OF SALINE OR WATER EXTRACT SUSPENSIONS (E) OF BIRD PITUITARIES APPLIED TO THE CROP SAC FOR 4 DAYS

Responses were evaluated by macroscopic and microscopic examination of the crop sacs and rated as follows: 0, no response; —+, suggestion of a positive response; +, minimal but definite positive response.

Abbreviations: M, male; F, female; phalarope pituitaries, Wilson's phalarope pituitaries.

Table 2. RELATIVE PITUITARY WEIGHT (PITUITARY WEIGHT IN MG PER 50 g BODY-WEIGHT; THE APPROXIMATE MEAN BODY-WEIGHT OF MALE WILSON'S PHALAROPES) IN BOTH SEXES OF BREEDING WILSON'S PHALAROPES AND TWO OTHER SPECIES OF BIRDS

Female Wilson's phalarope (28)	1.20 ± 0.04
Male Wilson's phalarope (60)*	1.50 ± 0.11
Female red-winged blackbird (22)*	1.81 ± 0.12
Male red-winged blackbird (20)	1.26 ± 0.16
Female Killdeer plover (29)*	0.86 ± 0.07
Male Killdeer plover (38)*	0.86 ± 0.07

Figures in parentheses indicate the number of birds examined. An asterisk denotes the sex which naturally develops a brood patch and incubates.

that, in birds in general, prolactin is the hormonal stimulus to incubation and brood patch development⁶, except in pigeons and doves where, since it controls crop sac development in members of this family, a special case is involved (see refs. 7 and 8).

It is evident from the findings given in Table 2 that in the first two species, in which only one sex naturally develops a brood patch and incubates, that sex has the higher relative pituitary weight. In the Killdeer, in which both sexes form brood patches and incubate, relative pituitary weights are similar. The unit of body-weight (50 gm), relative to which we have expressed pituitary weights in Table 2, is arbitrary but approximates the mean body-weight of the smaller of the two sexes in the first two species.

Further evidence in favour of greater prolactin production in male than in female phalaropes was obtained by a comparison of the number of acidophils per unit area of adenohypophysis in microscopic sections of this tissue from 3 males and 3 female red-necked phalaropes (*Phalaropus lobatus*), all in breeding condition. Acidophils were stained with acid fuchsin by a method previously described⁹. Mean numbers of acidophils per unit standard area (based on counts over 8 such areas for each bird, representing about one-fifth of the total area of the adenohypophysis cut at 5μ) were: males 236 ± 16.0 and females 125 ± 41.5. A paired *t* test applied to the data gave a *P* value for this difference of the means of about 0.08.

There is good evidence that prolactin is produced by fuchsinophilic acidophils in birds^{10,11}.

Relation of Population Density to Sodium Availability and Sodium Selection by Microtine Rodents

A COLLECTION of 55 published records of population densities of rodents of the genus *Microtus* reveals a strong correlation between levels reached at population peaks and local soil sodium-levels as reported in soil surveys or deduced from indirect evidence. In areas with low soil sodium the highest density reported was 230 animals per acre and populations exceeded 30 individuals per acre in only 12 (19 per cent) of 63 reports. In regions of inter-

mediate soil sodium, *Microtus* populations ranged up to 400 with 16 of 22 (72 per cent) reports listing more than 30 per acre. In regions of high soil sodium there were records in excess of 1,000 animals per acre and 30 or more (91 per cent) records were more than 30. Cyclic population fluctuations seem to occur in the animals regardless of sodium-levels, but the densities reached at population peaks are characteristically many times higher in regions of high soil sodium than in regions of low soil sodium. The correlation could be due to other ions associated with sodium in the soil. However, the possibility that it reflects a functional relationship between availability of sodium and population regulation suggested a series of laboratory experiments with meadow voles (*Microtus pennsylvanicus*) from a laboratory colony established with wild animals trapped at Madison, Wisconsin.

Two experiments were conducted to test the effect of restricted and unrestricted sodium chloride diets on reproduction and population growth. Eight 3' × 6' pens, each containing two males and two females, and eight 3' × 3' pens, each containing one male and three females, were established and left undisturbed for 15 and 19 weeks respectively. Alfalfa hay and whole oats were supplied in excess to all animals. Four replicates of each sex-group were supplied *ad lib.* with a 0.5 per cent NaCl solution and with distilled water; the control groups received only distilled water. Populations supplied with the NaCl solution produced 60 young in the 2 male groups compared to 43 and 64 in the restricted sodium diet groups (*P* less than 0.05, paired *t*-test). The groups with sodium *ad lib.* maintained a higher net population over the test periods (*P* less than 0.05, paired *t*-test).

In a second group of experiments segregated sex and mixed sex groups of 5- to 8-week-old voles were tested for self-selection of NaCl at various levels of crowding. They were provided with a choice of distilled water and NaCl solution in paired 'J' tubes, which were calibrated for direct measurement of daily fluid consumption. The series of tests were conducted: (a) high-density groups (8 animals per pen) and low-density groups (4 animals per pen) of each sex were compared directly; (b) 24 animals of each sex were subjected successively to four 14-day test periods with densities of 4, 8, 24 and then back to 4 animals per pen; (c) mixed-sex groups with one male and three females per pen were compared with groups containing two males and two females. High-density animals in test series a selected about 70 per cent (males) and 90 per cent (females) more of the NaCl solution than the low-density animals (*P* less than 0.01, paired *t*-test). In test series b NaCl selection varied directly with crowding when density was changed on the same twenty-four animals. This was most striking in males, where the ratio of NaCl solution to distilled water selected increased from about 2:1 successively to 6:1, 10:1 and back to about 4:1 with the return to low density. In test series c, groups consisting of two males and two females selected a significantly higher ratio of NaCl solution to distilled water (6.2:1) than did the groups of one male and three females (2.1:1).

Increased appetites for sodium shown by adrenalectomized laboratory animals have been considered to reflect an increased physiological need for this salt¹⁻³. This suggests that the higher selection of NaCl by our animals under conditions of continued crowding was a manifestation of sodium deficiency, perhaps due to inadequate adrenocortical regulation of sodium metabolism. The behavioural and physiological mechanisms by which sodium deficiency might affect reproduction in crowded animals is beyond the scope of this report.
